ADDRESS.

PRELIMINARY EDUCATION, PROFESSIONAL TRAINING AND PRACTICE IN NEW YORK.

Address before the sixth annual meeting of the National Confederation of State Medical Examining and Licensing Boards, Atlanta, Ga., May 4, 1896.

BY JAMES RUSSELL PARSONS, JR.

DIRECTOR OF EXAMINATIONS, UNIVERSITY OF THE STATE OF NEW YORK.

A few years ago the terms "American doctor" and "Philadelphia doctor" were current in Europe as synonyms for incompetency. This fact was most disagreeably impressed on my mind when as United States consul at Aix-la-Chapelle I was asked to testify in a case before the German courts touching the value of a Buchanan diploma.

The circumstances connected with this German trial were vividly recalled last month by one who seemed anxious to equal the record of Buchanan in selling medical degrees to all comers.

A young pharmacist who had never studied at a medical school asked me if I thought a medical degree from the Wisconsin Eclectic Medical College worth \$35. In response to my questions, he submitted certain letters, the first from the president of the institution which offered the diploma (see JOURNAL, Vol. XXVI, p. 838), the second, which we herewith give, from the Secretary of State of Wisconsin, answering a question asked by the young pharmacist.

DEPARTMENT OF STATE, MADISON, WIS., April 14, 1896.
Mr. —, Albany, N. Y.

Dear Sir:—In reply to yours of April 10, will say that the Wisconsin Eclectic Medical College of Milwaukee is a regularly incorporated company of Wisconsin. I know nothing in reference to its reliability. Would refer you to Dr. Walter Kempster, Commissioner of Health, Milwaukee, Wis., for information in regard to same. Yours very truly,

HENRY CASSON, Secretary of State.

The examination blank referred to in the first letter includes thirty-seven questions. Thirty-five dollars and a rudimentary knowledge of the purpose of a cathartic seem to be about the only requirements for an M.D. degree from this enterprising institution.

History repeats itself but with less frequency in this direction than formerly, and the evil resulting from this reckless distribution of diplomas is largely nullified because in thirty-five States and three Territories these diplomas no longer constitute a license to practice medicine.¹

In 1888 the United States was almost the only civilized country in the world that did not as a rule protect its citizens from the imposition of quacks. Many

of our distinguished physicians and surgeons were known and honored abroad, but the genius of the few could not atone for the incompetency of the many; in the absence of proper restrictions it was impossible for the American medical profession to attain a position of eminence.

Since 1888, when my testimony was desired by the German courts, how great the change! At that time only five States in the Union exacted an examination for license to practice medicine, and the laws in those States were crude, imperfect and for the most part inoperative.

A licensing examination is now required in twenty-two States. Indeed, if we count Texas, where laws conflict, the roll includes twenty-three.

In 1893 the Massachusetts Legislature passed an act requiring plumbers to be examined for license. After this the practice of medicine could not long remain unrestricted, and as a matter of course the law of 1894 followed.

At the present time there are laws to regulate medical practice in all States except New Hampshire. In this State not even registration is required.

Though Harvard shares with Johns Hopkins² the honor of first requiring college graduation as the preliminary education for M.D. degrees, we have long been forced to recognize on the part of New England lawmakers a singular indifference to provisions restricting the practice of medicine.

In "Customs and Fashions in Old New England" Alice Morse Earle tells us that in "1631, one Nicholas Knapp was fined and whipped for pretending 'to cure the scurvey by a water of noe worth nor value which he sold at a very deare rate.'" One is almost tempted to suspect that this whipping took as much out of the New England lawmakers as it did out of Mr. Nicholas Knapp, for since that remote date scarcely a rumor has reached us of any equally vigorous remonstrance with unqualified practitioners.

As a result New England has been a specially promising field for quacks, not many of whom were considerate enough to follow the example of the celebrated "rain water doctor." Of this worthy it is recorded that he "worked wondrous miracles and did a vast and lucrative business" till he opportunely ended his career by tumbling into a hogshod of his own medicine.

As already stated twenty-three States now require licensing examinations. Of these examinations, sixteen are before a single board; four before two boards, allopathic and homeopathic; three before three boards, allopathic, homeopathic and eclectic.³ In eleven States candidates for examination must be graduates of medical schools; in three of these eleven

¹ As I was about to leave Albany for Atlanta a letter reached me from Dr. Kempster stating that proceedings had already been instituted by the Attorney General of Wisconsin to revoke the charter of the Wisconsin Eclectic Medical College. He added that graduates of this institution were not permitted to register in Wisconsin. It seems impossible, however, to prevent the registration of worthless diplomas in those States whose laws require merely the presentation of any sort of a certificate of qualification to unqualified local officers.

² Recent action by the University of Michigan contemplates a similar requirement.

³ In Alabama each county has an examining board; in Texas and Florida each judicial district. Florida also has a general homeopathic board.

States they must have studied medicine four years; in two States they must have attended at least three courses of medical lectures, though a diploma is not required. One of these States, Minnesota, will require four courses but not a diploma after Jan. 1, 1899. In six States applicants must have a competent preliminary education, though the provision is indefinite except in the New York law.⁴ Montana requires of applicants graduating after July 1, 1898, four courses of six months each. In New York the increase from three to four courses of six months each takes effect Jan. 1, 1898, but does not apply to students matriculated before that date and graduated before 1902. In ten States the licensing examination is the only test of fitness for practice, plainly a much more unsafe standard than indorsement of diplomas from accredited schools without a licensing examination.

The laws of thirteen States and three Territories⁵ demand either approval of medical diploma or examination by State or other duly qualified boards.

Illinois, a type of this second class, has done much to elevate the standard of medical education in the United States.

This leaves only eight States and three Territories in which it is necessary merely to present the diploma or other certificate of qualification to unqualified local officers.

We do not contend that many State medical laws are satisfactory. Indeed with few exceptions they are far from perfect. But we do assert positively that the advance in this country since 1888 is without a parallel.

But I will not trespass on your patience by speaking more at length of State medical laws in general. It is my purpose briefly to call your attention to what has been done in New York since 1888.

The University of the State of New York, established in 1784, is one of our oldest institutions. It is not a teaching body but a State department and at the same time a federation of 640 institutions of higher and secondary education. Its administrative departments are five in number, Regents office, Examination, Extension, State library, State museum. Its objects, as defined in the University law, are "to encourage and promote higher education, to visit and inspect its several institutions and departments, to distribute to or expend or administer for them such property and funds as the State may appropriate therefor or as the University may own or hold in trust or otherwise, and to perform such other duties as may be intrusted to it."

To the examination department, organized in 1889, are entrusted all examinations conducted by the regents, including preacademic, academic, extension, higher, professional and technical. These examinations require annually 1,500,000 question papers, which are printed in the department on our own presses, by our own employees.

In all examinations under the University, as fully set forth in the academic syllabus, "it is the aim to test as far as practicable the thought-power of candidates. Definitions, rules, principles and laws are of little value without a knowledge of their applications."

The system of alternative questions is in vogue; the question papers are framed along broad fundamental lines, and, if students are adequately prepared, the chance of failure is reduced to a minimum.

The excellent results achieved by these examinations are largely due to the sympathetic cooperation of teachers and professional men throughout the State. Intelligent criticisms and suggestions are earnestly requested and always meet with careful consideration.

Academic examinations in 73 branches are held by the regents of the University in January, March and June in about 500 New York secondary schools; at the summer schools in August, and at central points in September, for professional and technical students only. They are also given once a year in other States when expenses are provided.

The method of conducting regents' examinations was prescribed in 1864. Since 1870 all papers claimed by principals as meriting 75 per cent. have been re-examined at the regents' office. In 1895 259,932 academic papers alone, not including those written by professional students, were submitted to the department. Of this number 28,701 or 11 per cent. were rejected.

The phenomenal growth of these academic examinations under the revised system of 1891 is especially remarkable in view of the fact that they are purely voluntary and that the University discourages all tendencies to over-examination.

The regents were not required to certify to the preliminary education of those seeking admission to any professional study till 1882, when the court of appeals adopted a rule that all law students, unless college graduates, must pass certain regents' examinations. These requirements were raised in 1891, and again in 1894.

The acknowledged value of the law student examinations led in 1889 to a similar requirement for medical students. This law was amended in 1893, 1895 and 1896. The statute that took effect March 21, 1896, fixes as the minimum preliminary education for medical degrees a registered four year high school course following a completed eight year elementary course.

After January 1, 1897, all matriculants for medical degrees must either be graduates of at least a registered four year high school course, or pass equivalent regents' examinations.

The registry list in the regents' office is constantly revised to meet changes in courses of study, and is the source of information in response to inquiries from all parts of the globe. An idea of the extent of this work is shown by the fact that credentials in 20 different languages were received last year.

July 1, 1895, the new veterinary law took effect and August 1, 1895, the new dental law, fixing the same preliminary education standard as that for medicine. Students may be matriculated conditionally provided the conditions do not exceed more than one year's work, but all conditions must be made up before the beginning of the second annual course counted toward the degree.

We see therefore that graduation from a registered high school is now the accepted New York standard for admission to professional study. In medicine, dentistry and veterinary medicine there is no exception. Pending another revision of the rules of the court of appeals, however, a law student unable to offer a three year high school course or its equivalent, may meet the preliminary requirement for admission to the bar by passing examinations in specified studies representing only two years of academic work.

In 1895 16,612 answer papers were written by can-

⁴ The New York standard has just been adopted by the Pennsylvania board of medical examiners.

⁵ Including Indian Territory, though the Cherokee Nation requires a licensing examination.

didates seeking admission to professional study, a growth of 106 per cent. in two years. 68.9 per cent. of these papers were accepted as compared with 59 per cent. of those written at the schools.

Between 50 and 90 per cent. of these professional certificates are granted without regents' examinations on evidence of the requisite preliminary education. This proportion will doubtless increase under the new laws till it becomes at least 82.5 per cent. as in 1893.

Graduation from a registered four year high school course after the completion of eight years in an elementary school approximates the highest standard adopted by any country in the world for admission to the study of law or medicine, and is fully equal to the requirement of any other government for dental or veterinary students.

In Germany the matriculant must have passed the Abiturientenexamen after completing the course of nine years in a Gymnasium. This examination presupposes as much work as is usually covered at the close of the freshman year in a registered American college. Dentists and veterinary surgeons must have passed the examination at the close of seven years in a Gymnasium or Realschule (*Zeugnis der Reife für die 1 eines Gymn. oder einer Realschule*).

In Austro-Hungary, Russia and Switzerland the requirements for matriculation to medical study are on about the same plane. In France the degree of Bachelier ès lettres (equivalent to graduation from a full high school classical course) and additional examinations in physics, chemistry and the natural sciences are required. A similar standard is maintained in Italy (*Licenza liceale*), Spain and Cuba (*Bachillerato* and a supplementary examination). In England the minimum test, fixed by the program of the British medical council is comparatively low, though many English students have either passed a matriculation examination in arts or hold the B.A. degree. In the Canadian provinces also the varying requirements do not represent in any case more than the completion of a registered three year high school course. The minimum test prescribed by the Association of American Medical Colleges is still lower and only includes a little more than one year of academic work.

We now turn to the consideration of professional training and practice in New York.

Of her twelve medical schools, four adopted a four year graded course in 1894 and five in 1895 and 1896. For matriculants after January 1, 1898, four years' study of at least nine months each, including four satisfactory courses of at least six months each in four different calendar years must be required for degrees by all medical schools in New York State. This minimum standard for the degree of M.D. is equal to that prescribed in Austro-Hungary, France and Germany.

There are more medical schools in the United States alone than in countries whose total population is six times as great, and yet less than one dozen of these medical schools in the United States have endowments corresponding to those so lavishly made to other educational institutions or in any way proportioned to their needs.

Under these conditions we must expect to find often low requirements both for matriculation and for graduation where the public is not protected by statutes which establish minimum standards.

To Montana belong the honor of first requiring for

admission to the State licensing examination a diploma granted after four courses of at least six months each to take effect for all applicants graduating after July 1, 1896. As previously stated Minnesota will require four courses but not a diploma after Jan. 1, 1899. The Association of American Medical Colleges including sixty-three medical schools in the United States will push on this movement by its constitutional provision for a similar requirement for M.D. degrees in 1899 or thereafter, though contrary to the New York law, students of dentistry, veterinary medicine and pharmacy may be admitted to advanced standing. It seems safe to predict that within a few years the minimum standard, now prescribed by the laws of Montana and New York will be adopted by all reputable medical schools in the United States.

The New York dental and veterinary laws require for degrees three satisfactory courses in three different years. The three dental schools and the two veterinary schools meet this requirement.

Though three years' study of law is exacted for admission to the bar except of graduates of registered colleges, who may be admitted in two years, yet five of the seven New York law schools still confer the degree of bachelor of laws after two years' work.

It is rather singular that both in preliminary education and in term of professional study, dentistry, and veterinary medicine stand higher than law. Some action will probably be taken in 1896 to correct this anomaly.

It may be easily shown that high standards have proved beneficial to New York professional schools. Let us take medicine as an illustration. Since 1891 when the licensing law took effect the number of medical students in New York schools have increased from 3,321 to 3,756, the number of foreign students from 1,556 to 1,706. The property of New York medical schools shows an increase during this period of five years from \$2,764,530.22 to \$4,061,293.59, the annual receipts from \$397,969.72 to \$460,043.97.

The report of the examination department for 1894 contained a review of medical education in the United States and in foreign countries. In this report it was stated on the authority of Dr. Pepper that the University of Erlangen in Germany grants an M.D. degree after a three-year medical course. We were specially gratified to receive in October 1895 a strong denial of the statement from the dean of the faculty of medicine at Erlangen, showing conclusively how carefully American medical reports are now scanned abroad. Perhaps the Germans anticipate retaliation for the terms "American doctor" and "Philadelphia doctor."

In medicine, dentistry and veterinary medicine licensing examinations are now required by law. All applicants must meet the prescribed preliminary education standard and must hold either a diploma from some registered school or a license from some foreign country.

The New York law forbids the registration by the regents of any school outside the State whose minimum graduation standard is less than that fixed by law for New York schools.

The University is responsible only for the preliminary general education of law students. Examinations for admission to the bar were not uniform till the creation by the 1894 legislature of a State board of law examiners, consisting of three members to be appointed by the court of appeals.

Another important advance in 1894 was the ruling of the court of appeals and of the regents that only those were to be considered college or university graduates who had successfully completed a satisfactory course of not less than seven years in advance of grammar school studies. This ruling is in direct accord with the following provision in the University law:

"No individual, association or corporation not holding university or college degree-conferring powers by special charter from the legislature of this State or from the regents, shall confer any degrees, nor after Jan. 1, 1893, shall transact business under, or in any way assume the name university or college, till it shall have received from the regents under their seal written permission to use such name, and no such permission shall be granted by the regents, except on favorable report after personal inspection of the institution by an officer of the University."

As the veterinary and dental laws did not take effect until July and August, 1895, respectively, we can not yet report the results of the first year's work. These laws are modeled closely on the medical law, and practically the same rules and regulations have been adopted for their administration by the University.

During the four years in which the medical licensing examinations have been given 56, 267, 390 and 606 allopathic candidates have been examined 8, 21, 51 and 60 homeopathic, and 4, 7, 4 and 11 eclectic, making a total of 1,485, of which number 291, or nearly 20 per cent., were rejected.

In this summary each candidate who fails is counted as often as examined. Thirteen hundred different candidates have appeared before the three State medical boards during the four years ending Aug. 1, 1895, of which number 106, or more than 10 per cent., have failed to secure a license.

This result is remarkable when we consider that admission to the licensing examinations presupposes the preliminary education required by statute and graduation with the degree of bachelor or doctor of medicine from a registered medical school.

The work of men long out of school compares favorably with that of recent graduates:

	Per cent. licensed.		
	1893	1894	1895
Examined on graduation	91.8	91	90
Examined after 1 year's practice.	93.8	90	82
Examined after 2 years' practice.	83.4	87	85
Examined after from 3 to 33 years' practice	89.2	77	87

In 1895, failures were as follows in the several topics: Physiology and hygiene 19, surgery 36, anatomy 48; therapeutics, practice and materia medica 59, chemistry 62, pathology and diagnosis 65, obstetrics 67.

It is remarkable that old practitioners do better in physiology and hygiene, anatomy and chemistry than in obstetrics, or pathology and diagnosis. The statistics at all events show that in the only subjects for which some have demanded two standards, the old practitioners do not need a special dispensation.

We have now reviewed briefly the present status of preliminary education, professional training and practice in New York. To what has been said may be added a reference to the new law, by which no one may hereafter serve as a certified public accountant who does not hold a certificate of qualification from the University.

The attitude of New York toward professional

training and practice is of special importance. In her law schools are about 1,500 students, or one quarter of the number in attendance on all law schools in the United States. In her medical schools are nearly 4,000 students, or one-fifth the total for the entire country. In other professions she is equally prominent.

From this brief statement of facts I hope you have gained clearer ideas of the progress New York has made in preliminary education, professional training and practice, especially since 1889, the date of the first law requiring a preliminary education for medical degrees.

ORIGINAL ARTICLES.

TREATMENT OF CANCER OF THE RECTUM.

Read by Title in the Section on Surgery and Anatomy at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY LEWIS H. ADLER, M.D.

Professor of diseases of the Rectum, Philadelphia Polyclinic and Post-Graduate College; Surgeon to the Charity Hospital and to the out-patient Department of the Episcopal Hospital. PHILADELPHIA, PA.

The question of what surgical procedure is justifiable in any given case of cancer of the rectum is frequently hard to decide, especially from the standpoint of relieving the patient the most with the incurrence of the minimum risk.

The recognized operations are four in number: Extirpation, colotomy, posterior linear proctotomy and curettage.

Extirpation.—The ideal method of treating cancer of the rectum would be by extirpation, as is done in cases of the same disease when the mammary gland is the seat of trouble; but unfortunately it is not often that the rectal neoplasm is discovered in time to permit the entire removal of the growth and of all glandular involvement; consequently, it is my belief, that the cases in which this operation is indicated will always be confined to a relatively small number.

Colotomy.—On the other hand, colotomy is quite practicable in a large number of instances and the benefits derived from its performance are thus minutely described by Dr. Chas. B. Kelsey (*New York Medical Journal* for November, 1892): "It relieves pain; does away with the constant tenesmus and discharges from the rectum, which by their exhausting effects are the immediate cause of death; delays the development of the disease by preventing the straining and congestion of defecation; prevents absolutely the complication of intestinal obstruction, which is another cause of death; enables the patient to sleep, eat and gain flesh, and often makes him think himself cured in spite of the plainest prognosis to the contrary. Instead of passing his days and nights upon the commode, wearing out his life in his effort to free the bowel from its irritation, he has one or perhaps two solid fecal evacuations from the groin in twenty-four hours." The foregoing description of the benefits derived from a colotomy is no exaggeration. It is the operation to which I would cheerfully submit were I a sufferer from cancer of the rectum which had reached the stage of operative interference. In this connection I would cite the following case, which I consider a typical one for the operation of inguinal colotomy: T. J. P., male, American, aged 52, clerk by occupation, first consulted me in 1893. At that time his history was as follows: Parents dead,

one at the age of 60 of pneumonia, the other of rheumatism at 80. Oldest brother died at 40, of gastric cancer. Patient the youngest of seven children. Was healthy as a child. Married at 40. With the exception of lumbago and several attacks of presumed malaria he has enjoyed good health up to present illness. Has been a moderate user of alcohol but an inveterate smoker. No venereal trouble. For many years has been constipated. His present trouble began about four years before his visit to me. The pain in his back which he attributed to lumbago became worse. His bowels became loose. In the morning he would have apparently a normal fecal stool and later in the day one or more watery passages. The movements were attended by considerable straining and a sensation as though the bowel had not been entirely emptied. The urine was voided frequently during the day and he was obliged to empty his bladder several times during the night. Later on, he noticed that his passages, when formed, were not as thick as they had been—but what caused him anxiety was the fact that he passed about a tablespoonful of an offensive bloody fluid several times daily and the movements were accompanied by severe pain over the sacrum. These symptoms becoming aggravated and the patient being unable to rest comfortably in any position, night or day, together with the fact that he was steadily losing flesh and had no appetite, led him to consult me. At this time examination revealed the following condition: Varicose veins of both legs, but much worse on the left side. Cachexia not marked. External and internal hemorrhoids noted. A growth was detected about four inches from the anus, which was quite hard and nodular. Its upper limits could not be ascertained. Consent was given to perform an inguinal colotomy. Under ether anesthesia, the usual incision was made into the abdominal cavity and the peritoneum was drawn up and attached to the skin by sutures. The colon readily presented and, at the site selected for the artificial anus, a loop of it was brought out into the wound and a glass rod, four inches long, was passed at a right angle to the line of incision under the colon, through a puncture made in the mesentery; this was done so as to fix the bowel in the desired position. The intestine was then sutured around the wound to the skin and parietal peritoneum; seven or eight fine silk sutures being used on either side and the last suture at each angle being placed across from one side to the other. The suturing of the bowel in this manner prevented the protrusion of the small intestine and consequent danger of strangulation. (Fatal results from this accident are on record.) The dressing consisted of gauze placed between the glass rod and skin, so as to prevent undue pressure, and the lower stratum of gauze overlying the intestine was soaked in carbolic olive oil, to obviate any subsequent adhesion to the bowel, from the lymph filling the meshes of the gauze, which is apt to ensue unless this precaution is taken.

The patient did well after the operation and convalescence was all that could be desired. The intestine was opened on the third day. In two weeks he was allowed to get out of bed and in another week to walk about generally. By means of a home-made abdominal band and the application of pledgets of old linen and cotton over the artificial anus, he had and still has no difficulty in controlling the passage of wind and fecal matter. A truss was obtained for him but

was not so comfortable as the abdominal support mentioned.

He gained flesh, was able to eat and sleep well and attend to his business. The pain and inconvenience previously suffered were greatly relieved. During this time opiates were occasionally required. At present writing (three years since the operation), and for a year past, he has suffered considerable distress from pain over the sacrum and has not been able to work. Opium has to be used daily. The growth has increased and causes considerable vesical disturbance. It is probable that the patient may live for six months or a year longer.

In an article read before the ASSOCIATION last year (Transactions, Surgical Section of the AMERICAN MEDICAL ASSOCIATION, 1895, p. 101-104), I went into a more extended discussion of the relative merits of extirpation and colotomy in the treatment of cancer of the rectum.

Posterior Linear Proctotomy.—I have never attempted to relieve malignant trouble affecting the rectum by means of a linear proctotomy. In benign stricture I have found it an excellent plan of treatment when combined with the subsequent use of bougies. Those surgeons who adopt this method for relief of rectal cancer speak highly of its efficiency, some going so far as to claim that it takes the place of both colotomy and excision. (Mr. Chas. B. Ball, F.R.C.S.I., Diseases of the Rectum and Anus, p. 336.)

Curettage.—In the present paper I desire to call attention to, and to emphasize, the value of curettage in those cases of cancer in which the disease is within the lower three inches of the rectum and its character of such a nature as to permit of its more or less complete removal by the curette. In selected cases the operation is followed by a diminution of pain, bearing-down sensations and discharge and the lumen of the bowel is enlarged.

Some patients object to having an artificial anus and refuse to have a colotomy performed; others consider the curettage of the growth a less dangerous operation and prefer a procedure which to them is less abhorrent than the idea of an artificial opening, in an abnormal position, for the passage of feces. In some of these cases curettage can be done with decided benefit.

In certain cases the combined operations of colotomy and curettage will afford the patient much more relief than where one or the other procedure is individually adopted. It is true that only temporary relief is afforded by either curettage or colotomy, but in the majority of cases this is all we can offer the patient under any plan of treatment in vogue at the present time.

During the past two years I have curetted the rectum for the relief of malignant trouble in seven different cases. In only one case was the operation deemed unsatisfactory. This was in a patient of Dr. D. F. Greenwald, of Philadelphia, with whom I saw the patient in consultation. I am indebted to the Doctor for the following history: "Mrs. R. was treated by me (Dr. Greenwald) for a recto-vaginal fistula about five years ago. At that time there was no evidence of contraction of the caliber of the bowel and no other symptoms pointing to the presence of cancer. For a period of three years following the operation for fistula she suffered no discomfort and was able to pursue her usual duties. Two years ago she complained of pain during defecation, which was

attended by a discharge of glairy mucus, streaked with blood. Before examination a decided decrease or narrowing of the bowel was discovered about two and one-half inches above the anus. Antiseptic douches and the use of rectal bougies daily benefited the case for more than a year. She then complained of bearing down pains and the countenance assumed characteristic carcinomatous cachexia. These symptoms continued with greater severity until you saw her. After the curetting operation she was unable to leave her bed, her appetite failed, emaciation followed and death from exhaustion ensued in two months and three days."

Even in this case, which was a most unfavorable one for any operation, the patient was much relieved of pain and the two months she lived were certainly passed with more comfort than would have been the case had no operative interference been attempted.

The results following curettage are best described by recording the history of a typical case: J. M., a colored man, age 33, by occupation an engineer, applied for treatment at our clinic, at the Polyclinic Hospital, about two years ago. Family history negative. Personal history negative except a possibility of his having had syphilis; this fact the patient denied, but the records at the Pennsylvania Hospital, Philadelphia, where he had previously been treated, indicate otherwise. Present trouble began some three years previous to his coming under my observation, with bloody discharges from the rectum and a feeling of distress about the anus. He stated that on two occasions during this time he had been admitted into the wards of the Pennsylvania Hospital and had the rectum cut, and that this was followed by the passage of bougies. He dreaded so much the passage of the bougies that on each visit to the hospital, he left as soon as he could obtain his discharge.

At the time he came under my care, he had a more or less constant bloody discharge from the rectum, considerable pain at stool and for sometime following the movement; he was very emaciated. Examination revealed a mass occupying the lower two inches of the bowel, part of the mass protruding through the anus. Abdominal palpation indicated the presence of nodular masses within that cavity, especially marked on the left side above the sigmoid flexure. At first he refused operative interference, six months later he consented to enter the hospital.

Upon admission to the wards of the Polyclinic and after the lapse of several days, the patient was prepared for operation and upon the day selected, he was etherized, the sphincters were stretched and the growth was thoroughly scraped away with a sharp spoon curette. A weak solution of permanganate of potash was employed for douching purposes. In some places scissors had to be used to remove the denser and more indurated portions of the mass. The bleeding at the time and after the completion of the operation was not alarming. The parts were fully dusted with iodoform and the rectum was plugged by means of a good-sized piece of gauze attached to a large rubber drainage tube, which latter had been closely fitted over a glass tube to keep it patulous, the rubber at the same time protecting the glass should it break by accident. Around the tube but within the folds of the gauze the packing was placed. The dressing was completed by a firm pad of gauze and cotton and a T bandage. Recovery from the operation was perfectly satisfactory, and in a month's

time the patient was given employment in the hospital as an orderly. He had not been able to work for over a year previously. The gain in flesh was marked. For a long time he was given the iodid of potash, but any increase above five grains, thrice daily, produced nausea; no good effect was noticed from its use. Four months later the patient was in such good health that he married. A short while after this event the growth in the rectum was noticed returning and the discharge reappeared. Some pain was also complained of and later defecation was accompanied by considerable distress and difficulty. Six months after the first curettage he was again subjected to a similar operation. Ten days subsequently he stated that he felt well and was free from pain. Graduated bougies were now used daily. A month later, marked tympanites suddenly appeared and the patient was unable to pass either wind or feces. Various laxatives were employed and several enemas administered before the bowels were made to move, which was not until the third day. Several similar attacks ensued which occasioned considerable trouble before relief was obtained. Finally, the patient became confined to his bed through sheer weakness, and death occurred from exhaustion about nineteen months from the time I first saw the patient. The autopsy revealed cancerous involvement of the liver and intestines.

In conclusion I would roughly summarize the indications for the operative treatment of rectal causes, thus: Extirpation, to be considered only in those cases in which the disease admits of the hope of obtaining a permanent cure; colotomy, when the rectum is involved above the lower three inches of the bowel and the disease has produced an appreciable obstruction; curettage or a posterior linear proctotomy, or the two combined, for those cases in which the disease occupies the lower three inches of the rectum.

GASTROSTOMY FOR STRICTURE OF THE ESOPHAGUS, BY THE SBANJEW-FRANK METHOD, WITH EXHIBITION OF PATIENT.

Read in the Section on Surgery and Anatomy at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY HUNTER P. COOPER, M.D.

PROFESSOR OF ANATOMY AND CLINICAL SURGERY IN THE ATLANTA MEDICAL COLLEGE, AND ATTENDING SURGEON TO GRADY HOSPITAL, ATLANTA, GA.

The patient, C. F. J., age 27, male, white, entered the Grady Hospital as a private patient in my service on Jan. 28, 1896.

The following history was obtained on admission: About one year ago he took one swallow of pure nitric acid by mistake, causing corrosion of the entire mouth, lips and esophagus. The mouth and lips healed about three weeks after the sloughs separated. Several months previous to admission the patient noticed an increasing difficulty in swallowing; in the last few weeks this has gotten considerably worse, and he feels now that small particles of solid food are stopped before reaching the stomach, evidently low down in the esophagus. Liquids can still be swallowed slowly and with difficulty; it takes him as much as half an hour to drink a glass of milk. At times during the past few weeks the contraction in the esophagus closes to such an extent that for two or three days at a time he says he is unable to swallow

anything: then relaxation occurs and fluids will pass into the stomach. His diet is entirely restricted to fluid food. On admission I find him fairly well nourished, pulse and temperature normal, tongue clean, appetite good and pulse regular. On examining the esophagus with bulbous bougies three strictures are detected seven, seven and a half, and eight inches from the edge of the incisor teeth, and no more are encountered until the instrument has passed thirteen and a half inches down the esophagus, when it meets with an obstruction which will not allow an instrument of any size to pass.

Treatment: For a number of days futile efforts were made to get the instruments into the stomach, but without success. The largest instrument that would pass the stricture seven inches from the teeth was of the size of a twenty-two French urethral bougie. Nothing would pass lower than thirteen and a half inches. It was decided, therefore, to do a gastrotomy, and the operation which was selected was the Sbanijew-Frank method. I trust I may be pardoned for briefly describing this method, as it is not familiar to everyone.

The incision is about a finger's breadth below the costal cartilages on the left side, over the stomach. The first incision, three and a half inches in length, goes down to the muscles; the muscles are then divided in the direction of their fibres by blunt dissection. The peritoneum is opened in a line parallel with the edge of the costal cartilages. The stomach having been sought for and withdrawn from the wound, is drawn strongly outward by a ligature passed through its walls. Traction is made on this ligature by an assistant until a cone of the stomach three or four inches long is drawn out of the abdominal incision. While the assistant holds this cone in position by means of the ligature, the base of the cone is sutured to the parietal peritoneum all the way around.

The next step in the operation consists in making an incision through the skin, superficial fascia and areolar tissue down to the deep fascia. This incision is placed one inch above the margin of the costal cartilages, and its direction is parallel to that of the primary incision. By blunt dissection communication is made underneath the skin and superficial tissues between this incision and the primary incision. Through this communication the apex of the cone formed by the stomach is drawn; the wall of the stomach is sutured to the skin and the stomach opened. The primary wound is closed, the muscles being sutured seriatim and the skin incision sutured last. The advantage of this plan is that it brings the stomach through the abdominal wall in an oblique direction; a part of the stomach is included between the edge of the costal cartilage and the skin, forming a valve as it were. This device prevents leakage of the contents of the stomach during digestion, and is a great advantage over the old method of making a direct communication between the stomach and the abdominal incision.

The operation was performed on February 11, Dr. Elkin being present and lending me valuable aid. The patient was put to bed in an excellent condition: and for the next four days his temperature ranged between 98.8 and 100.2 degrees. At the end of that time his temperature rose to 102 degrees and pus was discovered in the wound. This was evacuated on the 16th by Dr. Nicolson during my absence from the city, and after that the patient convalesced

without a bad symptom. The wound healed nicely. Feeding by means of the stomach proceeded every four hours, a catheter being introduced into the stomach for this purpose and only liquid food administered. I feel quite certain that suppuration was caused by the wound being infected by the escape of some of the contents of the stomach through the puncture made into its walls for the purpose of introducing the ligature. I closed this immediately on withdrawing the ligature by two or three Lembert sutures, but gas escaped quite freely before I effected a closure, and I am certain some of the secretions from the stomach got into the wound, producing infection. His fever from the suppuration lasted only five days.

The subsequent history of this case has been uneventful. He has gained in flesh and strength, and as you see, is perfectly nourished by means of the feeding through the artificial opening. A few weeks ago I began to try the passage of bougies through the stricture from above. During my absence from the city Dr. Elkin succeeded in getting a small bougie eighteen inches from the edge of the teeth. Dr. Ward, house surgeon of Grady Hospital, passed an instrument, 15 on the French urethral scale, twenty inches. On May 4 I passed No. 15 of the French scale, sixteen inches; in other words, two and a half inches below what was formerly an impermeable stricture. On the same day No. 22 French was the largest instrument which would pass through the stricture at seven and a half and eight inches respectively, from the edge of the teeth. It is my hope within the course of the next few weeks to be able to get through the strictures and divide them by Abbe's method. Of course, if this can be done the external opening into the stomach can be closed. There is so much cicatricial tissue present, however, that I fear it will be impossible to thoroughly divide it so that recontraction will not take place.

I should say in reference to this operation that the result is all that could be desired. The valve does its work very well, and there is practically no leakage at all. A little gastric juice exudes from the opening, but none of the contents of the stomach. He keeps a little pad over the opening to prevent the irritation, which the gastric juice causes when it comes in contact with the skin.

DISCUSSION.

DR. ROSENTHAL, Philadelphia - I have seen this operation performed by Dr. Thomas S. K. Morton. I would like to ask if there was any complication resulting in Dr. Cooper's case. I know Dr. Morton always fears this and gets his patients up as quickly as possible.

DR. THOMAS, of Pennsylvania - I would like to ask a question regarding the use of the Abbe ligature. If this ligature is used and the enclosure done away with, would not this stricture recontract and necessitate a repetition of the operation?

DR. FERD. C. VALENTINE - It might not be out of place to compare these strictures with urethral strictures. A French surgeon has presented 20,000 cases of stricture of the urethra treated by linear electrolysis and 200 strictures of the esophagus treated in the same manner. His instrument is that of a sound attached to a small guide in the shape of an esophageal tube with a curved tip of platinum on its inner concavity or outer convexity. When this has passed through the stricture he dilates from three to ten millimeters. This suffices to open the stricture at that one point sufficiently to begin a series of dilatations and make a useful canal.

DR. W. J. MAYO, Rochester, Minn.—I have had some experience in these cases and it seemed to me that Fenger's operation is the best for this particular class of cases. You make an attempt at retrograde dilatation. In two of my cases, I used Fenger's operation, but it is subject to great annoyance from leakage. The fact that one can make several attempts, however, is an important point. I do not understand how the Abbe string method can be used in this case. One of my cases was that of a child who swallowed some concentrated lime, causing a stricture which it was impossible to pass. I first employed esophagotomy and then made a gastrotomy wound. Although we were able to divide the upper stricture, we could not pass through the lower one and I then made Fenger's incision. The reason I refer to this is, that an oblique incision brings one in the direct line of the stomach, and through this I could nourish the child very well. External esophagotomy with a heavy sound inverted the stricture, and in that way we were able to pass the tube into the esophagus, which held the stricture firmly in place. In a short time we were able to close the external wound, but we continued the dilatation for some time. The second case follows Abbe's method more closely, and I got through the stricture at once and sawed it out. For fear that we might not have succeeded, we introduced a tube and the end of the string was carried to some extent, but we could not pass the sound afterward, as it seemed to catch in the folds. The Witzel tube enabled us to feed the child for a number of months. With regard to what Dr. Valentine says, anyone who has had experience in urethral or other forms of cicatricial stenosis knows that if you can get the probe in your work is done. I have looked this subject up very carefully, and especially in connection with LeFort's method, but found that he had not done much. He practically employed gradual dilatation with the aid of electricity, which to my mind does not mean anything. I congratulate Dr. Cooper on the result of his operation, which is very complete, and it is the operation of choice. While I do not wish to criticise the case, still I do believe that Fenger's incision and the direct wound in the stomach is better.

DR. VALENTINE, continuing—I wish to state that I know nothing about this subject as it relates to the esophagus. I have seen stricture of the urethra treated where a filiform could be passed only with great difficulty and precisely six months thereafter a No. 20 French went through the stricture without any pain or hemorrhage. This was done in Bellevue Hospital, New York, in the presence of a number of gentlemen.

DR. COOPER, closing the discussion—One good point about the wound is that if you should divide the strictures and they should recontract, you would have simply to reopen the stomach at the site of the former gastric fistula, and this could be very easily and quickly done. The other criticism in reference to getting into this wound, as you get into an ordinary gastrotomy wound, is not true. Your finger easily presses the tissues down. This method does not interfere with any technique should you wish to perform retrograde dilatation.

THE ABORTION OF GONORRHEA AND TREATMENT OF OTHER URETHRAL AND VESICAL DISEASES BY HY- DROSTATIC IRRIGATIONS.

Read in the Section on Surgery and Anatomy, at the Forty seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY FERD. C. VALENTINE, M.D.

PROFESSOR OF GENITO-URINARY DISEASES, NEW YORK SCHOOL OF CLINICAL MEDICINE; GENITO-URINARY SURGEON, WEST SIDE GERMAN DISPENSARY, ETC., NEW YORK.

In a paper¹ read before the Society for Medical Progress, January 11 and before a Wissenschaftliche Sitzung der deutschen Poliklinik on January 17 of this year, as much of the bibliography of hydrostatic irrigations as covered the requirements was touched upon.

In that paper I described an apparatus which did away with nearly all the objectionable features of these irrigations. I now propose to submit some

modifications which are the outcome of constant endeavor to so simplify and render safe the treatment of genito-urinary diseases, as to make at least the most frequent thereof available for the general practitioner.

The modifications of the apparatus I present, consist essentially in:

1. The substitution of a cast-iron ring to hold the irrigator. By this means, the irrigator can more easily be attached to any wall or bookcase.

2. A rubber tube made especially for this apparatus, doing away with the complicated connections, which formerly were necessary. The essential feature of this tube is that its lumen is a *quarter inch in diameter*, which enables the operator to easily overcome any sphincter vesicæ. The tube has expansions at both ends, the one to attach to the irrigator, the other to make the change of nozzles easy.

3. A stopcock nearly thrice as large as its predecessor. This prevents cramping of the hand, when frequent irrigations are required as must be made in the specialist's office. The lever of the stopcock's button now has three catches, by means of which three forces of stream are obtainable with no more effort than a slight motion of the thumb.

4. The shield's neck is enlarged and rough-ground within. This facilitates its being slipped over the nozzle, when attached to the hose, and also attaches it firmly to the stopcock. The apparatus as described is made as were its predecessors, by F. Alfred Reichardt & Co., of 27 Barclay St., New York.

As far as the surgeon is concerned, these alterations of the mechanism prove convenient to a degree which a comparison with my former apparatus at once reveals. As regards the patient, experience has demonstrated that the tension of the urethra, which was occasionally somewhat painful in new cases, is now more quickly overcome. This I attribute to the large caliber (one-fourth inch) of the tube.

The technique of these irrigations is not essentially modified by these improvements, except that now, in but very rare cases, is the patient required to breathe deeply and to strain, as if at urinating.

The theory upon which this treatment is based, can be outlined in a very few words. If the sole purpose of the treatment were to merely wash microbes and pus from the surface of the genito-urinary mucous membrane, such serious consideration would not be necessary. But as the microbes that we must combat deeply invade the tissues of the urethra, mere washing away of those which rest upon its mucous surface would prove useless. Manifestly we can not follow the gonococcus into the tissues, but by these very copious washings we cause the mucous membrane to take up large quantities of water. The resultant artificial edema, renders the urethra a bad culture-medium for gonococci. In practice, whatever may be our theory, the results are oftentimes more than astonishing.

The difficulty of obtaining statistics of gonorrhea, are all too well known. As I have shown in another paper ("When may gonorrheal patients marry?" *American Medico-Surgical Bulletin*, Oct. 1, 1895), gonorrhea is still too lightly viewed by the laity to make reliable data obtainable in large numbers. I may, however, cite from those cases which I could observe from the beginning of the muco-serous discharge in which gonococci were present. *Every one of these recovered entirely within thirty-six hours.* Cases in which the discharge had grown distinctly

¹The Technique of Urethral and Intravesical Irrigations, *Clinical Recorder*, February, 1896.

purulent, when not complicated, recovered within ten days. Chronic cases, which had lasted for months and years, recovered in varying lengths of time. The most marked case among these was that of a physician, who had persistently treated himself for gonorrhea (perhaps with reinfections and auto-reinfections) for twelve years. In two days the copious yellowish-green, blood-streaked discharge grew watery; in five days the gonococci disappeared; in eight days the discharge was entirely gone.

It may be well to explain here what is meant by "cured." After the discharge ceases, the patient is not treated for a week or ten days. Then, no discharge reappearing, he is ordered to drink at least twice the quantity of beer to which he is accustomed. No discharge resulting after another lapse of ten days, he is given a strong, irritating injection of nitrate of silver. If the resultant discharge, which lasts from eight to thirty-six hours, contains no gonococci all restrictions are removed, except that the patient is requested to bring the next seminal emission resulting from coitus condonatus, in the same condom. If this contains no gonococci, and anterior and posterior urethroscopy show a healthy urethra, the patient is discharged.

These experiences, not few in number, are from those cases in my private practice that were not complicated with other affections. In those, the cases were delayed by the complications, whose removal in many instances was aided materially by the irrigations.

Berthold Goldberg,² of Cologne, has most carefully compiled the literature of the subject. He finds that of the cases treated by systematic intravesical irrigation, 60 per cent. recovered in less than ten days, 30 per cent. recovered in two to three weeks, and 10 per cent. mischanced. One-half of this 10 per cent. was attributable to avoidable causes, disobedience of patients, repeated excesses, etc. The remaining 5 per cent. distinctly resisted treatment, but would still more have proved unamenable to other forms of medication.

Goldberg's experience and that of others lead him to conclude that carefully systematized irrigations with potassium permanganate: 1, are indicated when gonococci are present; 2, are contraindicated in acute inflammatory conditions; 3, permanently remove the gonococci in 95 per cent. of far more than half the cases, within one or two weeks, in any stage of the disease; 4, are reliable as a means of aborting gonorrhea; 5, the successes are due to coincident mechanical and chemic effects. This author adds that the irrigations may also exercise a genuine, specific antigonorrheal influence.

My investigations lead me to except only Goldberg's second conclusion. The contraindication in acute local inflammatory conditions would necessarily be in pain; this is easily and quickly overcome by an injection or two of cocain.

Several authors, notably among them my best of friends, Hans R. Wossidlo of Dresden,³ did not obtain such favorable results. An analysis of their writings shows that they either did not follow the treatment in that systematic manner these cases require, or were unfortunate in having intractable patients. Wossidlo, however, asserts that as means of aborting gonorrhea,

this method has the decided advantage of easy execution; that in acute and sub-acute gonorrhea it yields a large percentage of favorable results in as far as concerns stopping the purulent discharge and causing the gonococci to disappear; but that in chronic gonorrhea, it is not equal to Oberlaender's methodic dilatations.

I am glad to avail myself of this opportunity to express my obligations to Wossidlo for leading me to adopt Oberlaender's method, both of examining and treating the diseased urethra. The profession owes a deep debt to Oberlaender for his method, which does away with that odium upon physicians and long wearing source of grief to patients—chronic gonorrhea. But in its treatment, while I follow Oberlaender closely, I never neglect to add irrigations. The combination has invariably yielded most satisfactory results. These will be testified to by the many colleagues throughout the United States who have honored me by their confidence in sending me those cases, or who have so treated them at home.

But, aside of all other considerations, let us view the practical advantages of these irrigations.⁴ If the method is correctly followed: 1, the disease is cut short; 2, pain is stopped; 3, no complications ensue; 4, no hand injections are used, with their unreliability; 5, no drugs are given by the stomach; 6, the patient can not peddle prescriptions.

The last is as important as any. As in other diseases, the patient is likely to assume that the last prescription he received, even if it were a cough-mixture, is the one which cured his gonorrhea. He gives copies to his friends similarly affected; they do not improve and the physician's reputation is accordingly damaged.

These facts should cause this method to be adopted by all practitioners, especially now that its application is so easy, by the apparatus which I have the honor of demonstrating.

A discussion of all the diseases in which urethral and intravesical irrigations prove useful would carry beyond the limits of this paper. The most frequent ones need only be mentioned; to suggest many others:

Catheter-Fever.—Since I made it a rule to irrigate the bladder, by means of the apparatus herein described, after any instrumentation of the urethra or bladder, I have never seen a case of catheter-fever.

Corperitis, Folliculitis and Seminal Vesiculitis do not contraindicate irrigations.

Cystitis and Posterior Urethritis.—The posterior urethra being practically a part of the bladder, diseases of both these regions are best considered together. If the inflammation is acute it may be well to treat it in the usual manner; but as soon as the patient can bear them, careful, gentle, mild irrigations will yield most satisfactory results. In this connection it must be remembered that the mucous membrane involved is not only very sensitive to irritation, but that sudden

² Centralblatt für die Krankheiten der Harn- und Sexual-Organen, Band VII, Hefte 3 und 4.

³ Centralblatt für die Krankheiten der Harn- und Sexual-Organen, Band VII, Heft 2, 1896.

⁴ Swinburne, after averaging thirty irrigations a day for two years, concludes a paper on "Permanganate of Potassium in the Acute Stages of Gonorrhea." (American Medico-Surgical Bulletin, Feb. 1, 1896) as follows: "Yet with this method, crude as it has necessarily been, the results have been far better than with methods previously tried. While I do not claim a cure in all these cases, yet I do claim for this method: 1, marked lessening of discharge, so much so that it ceases to engage the patient's attention; 2, a shortening of the course of the disease; 3, relief from the many troublesome symptoms so often noted in the course of the disease; 4, almost never hear a patient complain of chordee; 4, far fewer chronic cases; 5, fewer cases followed by stricture; 6, fewer cases where instrumentation is required; 7, fewer cases of posterior urethritis; 8, fewer cases of epididymitis; 9, fewer cases having secondary invasions of the mucous membrane from other microbes; 10, a larger proportion of complete cures than with any previous method with which I am acquainted."

distension produces much pain. In chronic cystitis and posterior urethritis, irrigations are exceedingly well borne and yield excellent results.

Epididymitis and Orchitis.—Goldberg and others treat these cases with ointments and Zeissel-Langlebert-Casper suspensory bandages until pain has subsided, before irrigating. If the case is one-sided, I strap the testicle and irrigate at once. If both testicles are involved I use Wossidlo's method. This consists in applying the galvanic current, two to eight milliamperes, for from three to fifteen minutes daily. Then I apply a suspensory bandage and irrigate at once.

Neurasthenia.—This affection, from which no genito-urinary case is entirely free, yields as the disease is relieved; but even in pure, essential sexual neurasthenias, irrigations render the most surprising results.

Prostatitis.—Acute prostatitis may be left to subside, which it does very soon under appropriate treatment. It does not however contraindicate careful irrigations of the anterior urethra. In chronic prostatitis the gland should be emptied by daily massage through the rectum before irrigating.

Retention.—If a patient suffering with retention acquires gonorrhea, Goldberg deems irrigation contraindicated. I hold that such cases must be relieved with carefully sterilized instruments and the irrigations used.

Secondary Syphilis.—Patients affected with secondary syphilis are said to bear irrigations badly (Goldberg). This has not been my experience.

Strictures.—It would seem that the artificial edema we strive to produce in gonorrhea might offer danger of retention if the patient also has a stricture. In such cases the Oberlander method yields most brilliant results, especially when associated with irrigations.

Tuberculosis.—When tuberculous cases are not very low or in fever their gonorrhea can be treated as in other patients. Indeed, the very character of the disease should command hasty removal of the additional infection (Goldberg).

It is my hope that these roughly drawn suggestions will sufficiently interest practitioners to lead them to test this method of treating urethral and vesical diseases. If the results others obtain should promote further development of treatment by able men, suffering humanity will be benefited and I will have taken up your time to some purpose.

DISCUSSION.

DR. CHAMPION, Atlanta—Dr. Valentine demonstrated his method in my office yesterday and in a patient without a stricture, he succeeded. Only a No. 12 of the French scale could be passed. I have been using this method and see no reason why I should make any change. In fifty cases that have been recorded, only one case of epididymitis developed. I think every case of gonorrhea should be treated by irrigation.

DR. OLMSTED, Atlanta—I would like to ask about the time of irrigation, that is whether the Doctor irrigates as soon as the patient comes to his office or allows the acute symptoms to subside. Also whether he injects the bladder in all cases at once.

DR. ROSENTHAL, Philadelphia—I remained over on purpose to hear this paper and to discuss it. I have seen some very bad results from gonorrhea, and these results often lead to pus tubes, inflammation, etc., in women. Inflammations of Cowper's gland, the bladder and the ureters are serious complications and if we can remove the contagion we should certainly try to do it by trying all methods so as to see if there be any truth in the assertion made by any one. In Pennsylvania, we have passed a law which compels midwives to at once send for a physician upon the birth of children suffering with ophthalmia and we have institutions under State and Quaker supervisions for these affections. We have such authority as Dr.

Schweinitz and others who show that these cases are due to gonorrhea. In the report of 1,000 cases in the Philadelphia district, in every case it was found due to gonorrhea. I shall treat the next case of gonorrhea that I have in the same way as Dr. Valentine and hope that my result will substantiate his claim. If we can irrigate the urethra of a man successfully, for the sake of his wife and children we should use such means as we have seen to-day.

DR. THOMAS, Pennsylvania—I think from this demonstration to-day one would think it was a very easy matter to treat gonorrhea, but I would state that this is not the case. With regard to latent gonorrhea, I must confess I do not know what it is. Supposing a case comes to us with a secondary gonorrhea and there are lesions of the previous attack existing in the urethra. You can not cure that case in four or five days or even weeks, I do not believe that a cure is possible under any circumstances in two or three days. Now take gonorrheal ophthalmia, which is a condition right under your eye and finger. You can irrigate this conjunctiva several times a day and you can keep it cleansed for many months, but by this treatment, although you may control it to some degree in two or three weeks, it is not cured as a rule, even under the care of the most competent oculists in three weeks or even in six weeks. The acute disease may be over but there is some of the sequelae left that can be seen in the eyes. I believe that the method suggested is a very good one. It is one that I practice continually but not exclusively. Another excellent method is to inject the urethra, after first cleansing it, with a solution of nitrate of silver four grains to the ounce, once daily for two or three days, and then irrigate the urethra with some milder solution. I have followed this in nearly all of my treatments with considerable success, but I have not yet seen a case that was cured in two or three days. In secondary gonorrheas that come to us for treatment, you have to consider the pathologic conditions that remain from the previous attack and cure this before you can get a cessation of the discharge.

DR. WILLIAM PERRIN NICOLSON, Atlanta—I would like to ask how long the reaction is to continue, how soon it is repeated, and how long the first sitting occupies. As to the injection of the bladder without a catheter, I remember Dr. Hunter McGuire performing this with an ordinary Davison syringe more than twenty years ago.

DR. VALENTINE, in closing the discussion—I will send reprints to any of the gentlemen who may wish them in order that they may familiarize themselves with the methods. Dr. Champion said that he is not convinced that the method of irrigating without a catheter is an altogether desirable one, but I am sure he will not use a catheter again after reading the literature I shall leave with him. With regard to irrigating at once, if I did not there would be no treating of the gonorrhea and no time would be gained. Unquestionably, irrigate the moment the patient comes into your office after you have shown by microscopical examination that he has gonorrhea. Do not let the acute symptoms subside. If the disease is located in the anterior urethra, irrigate in the morning and again in the evening from one to three days. Then give one posterior irrigation which will irrigate the bladder as well. On the fifth or sixth day again irrigate the anterior urethra, morning and evening and say on the eighth day give another anterior and posterior. Dr. Rosenthal suggested that my assertions should be tested and I hope they will. There have been sufficient statistics given to prove its efficacy, a French surgeon having employed the method in about 20,000 cases, a German in 10,000 cases, Goldberg in 2,000 cases, Swinburne of New York, in an average of 30 cases daily for two years and my own experience numbers about 3,000. I thank Dr. Thomas for criticising me so severely. He is right in saying that it is not an easy matter to treat gonorrhea and we must always do with some degree of apprehension. By this method I think it is easier to treat than by any other. Dr. Thomas also said he did not know what latent gonorrhea was, and I must say I do not know what it is either except that it is a very convenient term. It really means the lurking of the gonococci without the manifestation of symptoms except under special exciting circumstances. During the sexual life, especially after marriage, the crypts, glands and follicles are more frequently washed out, and not only may they infect the urethra but in a number of cases they may carry contagion to the female. The Doctor states that gonorrheal ophthalmia is not cured in five or six weeks and this is true. You can not subject the conjunctiva to the hydrostatic pressure that you can the urethra. While the pathologic character of the conjunctiva resembles that of the urethra, it certainly is of a different character, and you would not care to induce the edema, which makes the urethra a fair culture ground for the gonococci. Again, Dr. Thomas states that he has not seen a case

that he could cure in five days, and I agree with him that they are rare. We should not call it gonorrhea unless we have first found the gonococci. The experiences of men who have worked in this matter much more than I have shows that the cases are cured. A Berlin surgeon, who does not consider my method alone, says that it was successful under circumstances like those we have discussed. Dr. Nicolson asks how long the edema lasts, and I would say from three to five days. He also asks when I irrigate again: at the next sitting; ignore the edema. I was delighted to find that I could not claim priority in irrigating the bladder. I may be permitted to mention that Dr. J. B. Crossfield did this operation in the year 1791.

PLASTIC SURGERY.

Read in the Section on Surgery and Anatomy at the Forty-seventh Annual Meeting of the American Medical Association held at Atlanta, Ga., May 5-8, 1896.

BY F. W. EPLEY, M.D.

NEW RICHMOND, WIS.

Recent developments have shown, I believe, very clearly, that in the light of modern surgical methods we have not been living up to our privilege in our operations upon the surface of the body. The wonderful field which antiseptic and aseptic methods have opened up to the operator within the cavities of the body has so occupied the attention of the aggressive surgeon, that surface surgery has to a considerable extent been neglected.

This I believe to be due, partially at least, to the unwarranted warning which came to us from high authority soon after the advent of antiseptics, that they could not be used in plastic surgery, or at least in grafting, and further, that local anesthetics, such as cocain, were inadmissible. If this were true, we might be excused for accepting it and contenting ourselves with the infinitesimal groat of skin which we have been wont to plant in its regular orthodox one-half inch from the sound skin, and one-fourth inch from its fellow invader. But fortunately it is not true. Neither is it true that we must use split leather in a saline solution, "à la Thiersch," to repair our hides which have suffered a solution of continuity. On the contrary, experience teaches us that the whole skin, clear down to the cellular tissue, is at our disposal for this work, and further that we may and should use antiseptics and local anesthetics freely in our deliberations. And last but not least, we find that *the size of a piece of skin which can be successfully transplanted is limited only by our facilities for obtaining and properly handling the same, and the size of the space to be covered which can be brought into proper condition to receive it.*

Further, we can not by taking thought add a cubit to our stature, but we can, by a little thought, save the generous donor of one of these large pieces of skin a vast amount of annoyance, discomfort and pain, by making the pieces of skin removed boat-shaped at the ends instead of square, thereby enabling us to close the ugly wound at once with a continuous suture, leaving only a straight seam which will heal by first intention instead of leaving a wide, square, open wound, with no expectation of healing whatever, apparently, and which will sometimes exhaust the patience of all parties to the transaction.

In proof of these statements, allow me to report a case: On June 27, 1894, G. H. a car-sealer, had the whole bottom and flesh on the sides up one-half to one and one-half inches torn from his foot by a car wheel passing over it. Not only the skin but all the flesh was torn from the bottom of the foot leaving the bones bare so they could be counted. The os calcis

was left as bare and white as a porcelain door-knob. In addition to this the skin upon the top of the foot was bruised in a shocking manner so that nearly all the epidermis up to and above the ankle joint turned black and eventually came off. Strange to say only two bones were injured and they were small ones and only to a limited degree. After careful examination I decided to try what modern conservative surgery could do and declined to amputate. The foot was anesthetized by injections of a 4 per cent. solution of cocain and great care taken to make it clean, to remove all the tissue injured beyond repair and keep it antiseptic. Soon granulation tissue sprang up and covered all the bare bones. This was allowed to grow until the bottom was well cushioned over, when the foot was kept in proper shape by careful bandaging. On July 30, about a month after the injury, I began skin grafting in the usual way, placing small pieces of skin about the size of one-half a kernel of corn about one-fourth inch apart and about the same distance from the healthy skin all around the edge of the same. This process was carried on successfully until the sole proper was reached, when a different method was adopted in order, if possible, to avoid contraction of the skin and as much as possible to do away with scar tissue which experience has shown will not support the weight of the body. To accomplish this desirable result I resolved to try to transplant solid skin. Accordingly, on August 26, two months after the accident, a piece of solid skin two inches wide and over three inches long was removed from the calf of a friend's leg and placed across the ball of the wounded foot. This was a perfect success. So much that at the end of a week on cutting this transplanted skin the patient's blood flowed from it freely. On September 3, a piece of skin two inches wide and five long was taken from the arm of another friend, each piece being about one and one-half inches wide by five long. These transfers were followed by the same gratifying results, every vestige of skin removed retaining its vitality and growing firmly to the injured member. On September 9, fifteen large grafts about the size of a good kernel of corn were taken from my son's arm to cover two small corners not covered by the larger pieces. All these transfers having been so successful I decided to proceed to cover all the remaining surface, not covered by skin, at the next sitting. This was done on September 16, when one piece two by five inches and another two by five and one-half inches were taken from the arms of two more friends and the whole foot was covered. Every transfer was successful and in all fifty-two square inches of skin had been transferred in six large pieces from five different donors, and is to-day part and parcel of George Hibbard's anatomy. Beside, more than 300 smaller grafts from four other donors, making in all nine different contributors to the scientific repair of a railroad injury. And every one of them would willingly contribute as much more for the same purpose should occasion require. The skinning process was entirely painless, the healing rapid and the scar insignificant. The size which I have found most practical is about two by five inches. The best place to obtain it is just below the insertion of the deltoid muscle. This is not a very sensitive locality, is easily dressed, the skin is of proper thickness and texture and well supplied with blood vessels, while the wound here gives least annoyance to the donor.

Operation.—The donor should be seated in a com-

mon chair. His arm should be made aseptic in the usual manner; then antiseptic with a 1 to 1,000 bichlorid solution. Eight punctures with an hypodermic syringe should be made just outside the line of the proposed incision and about fifteen minims of a 4 per cent. solution of cocain, freshly prepared with sterilized water, injected into each puncture. Ligate the arm just above the elbow, not too tightly. Now surround the arm with several layers of gauze wet with 1 to 1,000 bichlorid solution. Place the patient in a position which will bring the wound in good light and most accessible. It must be *perfectly clean*, then rendered antiseptic by the free use of 1 to 1,000 bichlorid solution. It is most important that all weak granulation tissue be scraped gently, or shaved off, and open mouthed vessels oozing bright blood, in every part of the space, should be covered. Now bind, not too tightly, a pad of gauze wet with 1 to 1,000 bichlorid solution closely to the whole oozing surface and the wound is ready. When this is removed the surface will be clean and free from blood, all clots having been caught in the meshes of the gauze. Now remove the gauze from the donor's arm: put the skin upon the stretch, quickly block out the piece to be removed by cutting *clear through the skin* down to the cellular tissue. Carefully dissect up the upper point of the boat shaped area, securely fasten the hooks on the skin fork into the end of the flap, and as the skin is carefully cut, not torn or scraped, away from the subcutaneous tissue, roll it upon the skin fork, care being taken to roll up nothing but the skin free from blood clots or fatty tissue. Again, bind up the donor's wound with the bichlorid soaked gauze and he can wait until you have time to attend to him. Now remove the pad from the patient, apply the free end of the roll of skin to the wound and quickly unroll it upon the raw surface. If it does not fit it matters nothing; let it extend over upon the skin of the patient. It will live so far as the surface is denuded and the surplus skin will die and can be trimmed off later. The graft should be neither stretched nor pinched, but gently unfolded and smoothed out. Over this apply strips of rubber tissue just taken from 1 to 1,000 bichlorid bath; over this sprinkle a thin coat of iodoform, and then the usual gauze dressing, care being taken not to slide the graft upon its bed or bind it too tightly—just sufficient to make it secure. Now remove the gauze from the donor's wound and carefully draw the edges of the skin together with either a continuous suture or interrupted sutures closely put, dust with iodoform, cover with protective, reinforce the sutures if necessary and dress with gauze. Skin transplanted in this manner and cut forty-eight hours later will bleed even when placed upon the sole of the foot.

I wish to lay special stress upon three things, in closing. Use antiseptics freely, if you wish, cocain fearlessly, and make the donor's wound boat-shaped. The skin fork spoken of and the knife for removing the graft which I have devised, I have with me and will gladly exhibit to any who may wish to see them.

DISCUSSION.

Dr. J. McFADDEN GASTON, Atlanta, Ga. I would like to supplement one or two points in connection with these papers but not to enter into the discussion. It strikes me forcibly that with the advanced views we have in regard to antiseptic treatment of wounds and the aseptic treatment of wounds, that we should dispense with the use of corrosive sublimate which is suggested in the first paper and referred to in the second. The gentlemen who have the most advanced ideas of aseptic

surgery do not use this substance and I would like it illustrated how far it should be relied upon to correct deformities of this kind. I once encountered a case where the entire sole of a foot was torn off. I do not remember whether the bone was denuded or not. I depended upon traction with adhesive strips to bring the edges together and ultimately a very small surface was left for granulation so that the result was good. In another case of extensive laceration of the head and neck I dissected flaps from the shoulder, drew them up and connected them with the edge of the skull and by this traction succeeded in covering the part which had been denuded. I wish to call attention to a method that has not been alluded to and in fact has been overlooked to a great extent. Dr. Wilson of Louisville, published the method about fifteen years ago. It is to use the inner membrane of the egg for a granulating surface and by its use granulations are set up and you will usually get good results. Since its publication by Dr. Wilson, there has been a reappearance of the article drawing attention to the idea as having been introduced by a German. My experience with this method is limited but it has been sufficient to satisfy me of its efficiency. I remember one case in which I materially lessened the surface for granulations by this method.

Dr. EPLEY.—With regard to the use of corrosive sublimate, it has been deprecated I know, but I have found it of vast advantage sometimes. It has been my experience that skin transplanted in the way I mention would grow notwithstanding the fact of the number and size of the pieces. This method is of great advantage where you wish to preserve the elasticity of the skin. By all other methods with which I am acquainted you lose the elasticity of the true skin.

A TRIBUTE TO THE MEMORY OF EDWARD JENNER.

FORTY YEARS OF PERSONAL EXPERIENCE IN THE USE OF
VACCINATION FOR THE PREVENTION OF
SMALLPOX.

BY CHARLES N. HEWITT, M.D., M.A., LL.D.

PROFESSOR OF PUBLIC HEALTH IN THE UNIVERSITY, AND EXECUTIVE
OFFICER OF THE STATE BOARD OF HEALTH OF MINNESOTA.

The truest homage one can pay to a discoverer is personal and successful trial of his discovery.

I have had exceptional need of help in dealing with smallpox in more than 100 outbreaks of that disease during forty years of active practice of my profession. The experience began in private practice, was considerable while a surgeon in the army during the rebellion, and has been very large in twenty-four years of service as executive officer of the Minnesota State Board of Health.

Minnesota has had a large and steady immigration, both foreign and domestic, which has brought smallpox into townships, villages and cities, as into lumber camps and among the Indians.

One of the epidemics numbered over 300 victims, two others exceeded 100 each, but the most were limited epidemics.

For the last five years the disease has been almost wholly confined to the first affected. No more epidemics can occur in Minnesota, nor other than very limited local outbreaks, under our present methods of control, of which the essentials are positive knowledge of the facts, vaccination and re-vaccination, with isolation of the sick and suspects, and disinfection of persons and things.

The authority and responsibility of the State and local Boards of Health are mutual, and are recognized and insisted upon by the people.

In most of these outbreaks the writer has personally visited the victims as he would sufferers from any other disease, taking no precaution except to avoid being the carrier of the infection to other people. His personal exposure has necessarily been frequent and prolonged, but he has, with a confidence justified by the results, relied upon the protection afforded by

a vaccination with humanized lymph, done in infancy, and not, successfully, repeated since. To my mind this frequent exposure, and entire immunity from infection, are the most positive evidence I can give of the value of vaccination and of my absolute confidence in it. No other means of protection were used, and every known means of infection, except direct inoculation, were deliberately permitted.

There is a noteworthy reason for formally recognizing the value of vaccine at this time, beside the fact that it is the centennial of its discovery.

Professional opinion has been driven, by the wonderful discoveries of modern pathology, and the dogmatic assumptions founded thereon, to the belief that every specific disease has not only a specific cause (a self-evident fact), but that such specific cause is so, because it is a *particulate, pathogenic, living* vegetable or animal, or the *product thereof*. In small-

controlling its spread at that time), they could not "take" the smallpox but were in fact protected from it. Jenner verified this fact, and then went on to demonstrate that inoculation with cowpox, by the insertion of a bit of its peculiar product, vaccine, under the skin of a human being, induced the disease itself, which ran a peculiar and harmless course, and that such a person was not only protected from the direct inoculation of smallpox (as the dairymaids had discovered), but "from catching it" in any other way, and that the protection, probably, lasted for lifetime. He distinguished cowpox from other diseases of cattle; described perfectly the progress of the disease in man, the appearance of the vesicle day by day, its gradual decline, dessication and falling off, with the typical appearance of the scar it left. The illustrations and descriptions in the first edition of his book can not be surpassed to-day.

EDWARD JENNER.

pox and cowpox the specific causes are as much mysteries to-day as in Jenner's time.

The only explanation offered by a representative bacteriologist, so far as I know, was by Pasteur in his eulogy of Jenner, when he stated that we only lacked the proper culture medium, for as the bacteria of tuberculosis, enteric fever, etc., were discovered in this way, it could only be a matter of time and improved laboratory processes when these specific microbes should be discovered also. That discovery has not yet been made for smallpox and cowpox.

The foundation fact for Jenner's work was this: For many years the dairymaids of Gloucestershire had observed that if they took the cowpox from the cows before they came to be inoculated for the smallpox (the customary way of reducing its malignancy and

Of no other discovery in medicine can it be said so truly that the statements of the discoverer *remain facts* one hundred years after, though submitted to the criticism and trial of all the nations of the earth.

The modifications which experience has suggested are in details only:

1. That at least four perfect vesicles should be secured, as increasing safety and permanence.

2. That as smallpox sometimes recurs, even after a severe attack, so (but always in a modified and comparatively mild form) it may happen after successful vaccination, and therefore vaccination should be repeated after puberty, and whenever one is directly exposed to smallpox.

Jenner's rules were very simple and may be summarized as follows:

1. Be sure of the purity and activity of your vaccine.

2. The patient to be healthy, the operation to be carefully done, and the vesicle preserved unbroken, and allowed to run the natural course till the crust fall off and leave the perfectly healed scar.

3. To take the vaccine for use not later than the eighth day and from a typical vesicle.

Under these conditions I have put vaccination to very severe tests, under diverse conditions, upon great numbers of people, of all ages, occupations and nationalities, alone or in co-operation with my professional brethren.

The result has been that it has proved a safe reliance, has never been the carrier of other disease, and has never failed to prevent the spread of smallpox, when used as directed.

Even when used within four days after exposure to smallpox, it has modified that disease, diminished its danger and the subsequent pitting. I have always produced my own humanized vaccine, or obtained it from professional friends who used the same methods. As to calf lymph, this course was impossible, and I have frequently been deceived. In a long experience I have never seen other infectious disease associated with humanized or calf lymph, *collected under proper precautions, and used as Jenner directed.*

Up to five years ago I used humanized vaccine almost exclusively, but had sometimes to resort to calf vaccine, the best I could find, till I could establish a supply from infants, which I never fail to do when dealing with a smallpox outbreak.

Humanized vaccine by "arm to arm" transfer is still the favorite method. I think, among the public vaccinators of Great Britain, and when I was in Dublin in 1889 I saw typical vesicles upon the arms of children, produced by vaccine which had come in that way from the first supplied by Jenner himself a century ago. I make this statement on the authority of the Local Government Board of Ireland by its secretary. As for myself I have no evidence that humanized vaccine loses power by transmission through healthy children, and I believe that it does not.

While abroad, at the time referred to, I visited and studied the processes of cultivating vaccine, of both varieties, in all the leading stations in Europe and brought back with me calf lymph with which I began its cultivation, for our own use, in Minnesota.

I have been reasonably successful, having produced many thousands of points, and tested the vaccine upon nearly 2,000 children with no other than typical results. It has been supplied to many Boards of Health, and physicians who have reported to me over 50,000 results, which were normal with few exceptions, in which they were associated with broken vesicles or crusts torn off before the scars had formed. My experience with calf lymph has been favorable, while its manageable production, facility of preservation, and the professional preference for it, have made its cultivation a necessity.

For all that, I freely declare my own preference for vaccine from healthy infants, as in my experience, more generally active, prompt, and operating with less severity than calf lymph. As noted before, I always use it in the presence of smallpox, being able to get it directly from the infant within nine days.

It is very unfortunate that medical men permitted themselves to be drawn into the controversy inaugurated when the commercial production of "heifer vac-

cine" began in this country. Its motive was not so much truth as to displace humanized vaccine. The profession has the right to assume as much honesty on the part of producers of humanized lymph, as of animal, and that neither product will be put on the market except as it has proved to be typical by every test which practical experience has suggested. That, honestly done, both varieties of lymph will be found reliable.

I know, from ample experience, the truth of the above statement, and that there is no difficulty to one familiar with either form of culture in judging the quality of the product by an examination of the vesicle at the proper time for collecting the virus.

It must never be forgotten that cowpox is as real a disease as smallpox—Jenner thought them identical—and that vaccine is the product of disease, which inoculated into the human body reproduces cowpox. There is no dodging this statement, and yet some producers and physicians imply that it is not true by the carelessness with which they handle vaccine, perform vaccination, and deal with its normal results or the "accidents" which, in careless hands, sometimes follow it.

Vaccination is a surgical operation, slight certainly, but sufficient to admit dangerous infection should it accompany the vaccine. Very rarely does "accident" happen in this way, for (a rule with few exceptions) it is only when the vesicle is broken; its normal development interrupted, and an open, irritated wound replaces it, that other infection may come in and cause serious complications. For these the vaccine is no more to be blamed than the careful surgeon's knife under similar circumstances.

To avoid these so-called "accidents" is as important as the selection of the vaccine, because they may not only cause pain and needless suffering, but destroy the virus or interrupt its operation.

I have had occasion to examine so-called vaccine scars upon persons who responded to vaccination or smallpox in a way proving that they had no vaccine protection at all. The notion that any irritation which follows the use of supposed vaccine, or any scars which concludes such irritation, is proof of vaccine protection, is as absurd as to gauge protection by the severity of the result, and the size of the scar, though this is a common opinion.

The fact is that the typical vesicle, or scar, of Jenner can not be secured by the customary method of operating.

I will state the method which I find to be the best after many experiments. Its advantages are as follows:

1. To reduce the danger of wound infection to zero.
2. To produce typical vesicles and only as many as are necessary for the greatest protection and durability of result.
3. That the scar may be typical.
4. Preferred location front of left arm, or crown of shoulder.
5. The vaccine should be fluid when used and the wound thoroughly dry before clothing is replaced.

To secure these self-evident advantages use a new cambric needle as the instrument. In the clean skin make five little pricks just deep enough to start the blood, and about an inch apart. Then with the point of the same needle, charged with the virus, gently prick it into each wound, carefully. The pain need not "wake the baby," and the wounds will be closed

in a few minutes, and healed in six hours. In this way infection by wound is practically impossible. In thirty-six hours all traces of the operation should be gone. In about thirty-six hours more, if the vaccine is to "work," a "mosquito bite" appears over the site of each wound; that gradually increases into a little vesicle, which in turn is surrounded by a zone of redness, and if typical, on the eighth day the two resemble a "pearl on a rose leaf," as Jenner described the vesicle of this time at court. On the ninth day supuration occurs, constitutional symptoms begin to appear, with increased local redness and swelling; by the twelfth day these diminish, the areola begins to fade, the soreness decreases, and the vesicle discolors and dries up. When the wound is entirely healed the crust falls off, leaving the characteristic scar. Of course the operator has *clean hands* and takes the same precautions as in other important surgery.

Using the simple method above described, I have never had any serious "accident" and never saw an instance in which there was any evidence of other infectious disease having entered the body *with the vaccine*. I have seen a few cases in which a broken vesicle had opened the way for septic poison and bad results had followed, but none in which such results was not the direct consequence of injury. Any instance in which septicemia in any form occurred, has been, in my experience, of this character.

These facts are so because, with us, the same care and precautions have been taken *in using* as in *collecting* vaccine. Until medical men will insist upon the same rules and use them in their own practice, the present professional and popular distrust of vaccination will not only continue, but increase, as it ought to do.

It is proper that I should state the method by which I have repeatedly been able to overcome opposition to vaccination in the presence of smallpox. Argument in the ordinary sense is useless, nor does it seem to be worth while to spend breath and patience in that way. I state my personal confidence in the necessity of the operation, and prove my faith in the vaccine by offering to be the first to submit to its use. Such evidence has never failed to persuade even the most ignorant and obstinate, and has inspired a confidence which has amply repaid the slight trouble involved.

It is well not to forget that the secret of Jenner's discovery was really found in the experience of the laboring class, who most need its beneficent modification to-day.

There are many physicians and health officers who, appreciating existing difficulties, are urging compulsory legislation and a fine of parents for neglect of vaccination of children. I trust they have studied the history of such legislation and watched the effect in England where the compulsory law is openly violated to-day because of the opposition created by itself and by blundering attempts at its enforcement.

My experience has been large enough to enable me to have an opinion founded upon it, and I unhesitatingly declare for no other legislation than the power to isolate as for any other infectious disease. That is all we have in Minnesota, though the legislature has more than once been willing to go further if requested. The results of our present methods appear in our published experience of their use, in a steady reduction of smallpox prevalence from the beginning to date, though the disease has been epidemic more than once in adjoining States since it assumed the form of lim-

ited endemics, and often what may be called "family outbreaks" in Minnesota.

If we can overcome prejudice fostered by controversies as to forms of vaccine, and the notorious accidents which have followed the use of commercial calf lymph at various times, there will be no difficulty in reestablishing infant vaccination as a habitual custom again, and making a certificate of successful vaccination a necessary prerequisite to admission to all schools, *on the demand of the people themselves*.

It is fortunate that the claims of vaccine rest upon a long experience, both popular and medical, of their usefulness in actual service. It is not a laboratory product, and not comparable with antitoxin for diphtheria, for example, as it does not involve intricate artificial processes of production or use. It is a result of common experience in the dairy and the stable, carried to positive demonstration by Jenner in common experience too. Its value has been tested as no other agent for prevention of disease ever can be.

Its value is simply this, that its proper use has stayed the progress of a great plague. That use is one hundred years old to-day. Smallpox, a *terror* one hundred years ago, is to-day, *because of vaccine*, the most easily controlled of all infectious diseases.

In a dark and secluded place near the great west doors of Gloucester cathedral stands a statue of Jenner. When I saw it in 1889 it was covered with dust and had every appearance of neglect. In the city of Gloucester, near where Jenner lived and made his discovery, and where I think he at one time practiced his profession, the anti-vaccination party have, within a few years, won what they call a victory, and deprived hundreds of children of the protection against smallpox, which, *in that city*, was peculiarly their birthright. Medical men and health officers warned the authorities that it was only a question of time when the plague would be upon them. It is there to-day, in the centennial year of the discovery of vaccine, and too late to prevent, but not too late to crush out the disease; vaccination is again in urgent demand and imperative use.

When the fight is over, the dead buried, the disabled and deformed provided for, the least that the people of Gloucester can do will be to punish those who have so grievously misled them, clean and beautify that statue of Jenner, add another grateful inscription to its base, sing a Te Deum, and publish their reconversion by terrible and needless experience to the belief that vaccination for the prevention and control of smallpox is the most clearly demonstrated fact in the history of the management of disease.

THE DISCOVERY OF VACCINATION.

Address delivered at the Centennial Celebration held at Atlanta, May, 1896.

BY JEROME COCHRAN, M.D.

MONTGOMERY, ALA.

Great is the name of Jenner. It marks an important historical epoch. Before Jenner, smallpox was king—king in the palace and in the hovel—king all the time and everywhere. In civilized Europe it claimed annually many hecatombs of human lives. After Jenner vaccination was king, and under the protection of its invulnerable armor men and women were enabled to walk in the midst of pestilence with impunity. Such and so great was this man's discovery. No wonder that his fame comes to us resound-

ing down the corridors of time. No wonder that in the catalogue of great doctors he stands out in bold relief as one of the greatest. He has, perhaps, done more for the salvation of human lives than any other man that ever lived.

But a truce to panegyrics, and now to our problems.

Smallpox is the type of specific infectious diseases. It runs a definite course, can not be cut short by treatment, and one attack, in the immense majority of cases, protects the entire system against subsequent invasion. Nevertheless, second attacks are not unknown. I have myself seen one case of a patient who recovered from a first attack of confluent smallpox and afterwards died of a second attack a few years later.

Of the physical character of the smallpox poison very little is known, and I touch upon this point very briefly, because I believe it is to be treated of specially during this discussion by a distinguished bacteriologist. But we do know something about it. We know, to begin with, that it is organic and living, because it is endowed with the faculties of growth and reproduction; and we know that it is composed of semi-solid, colloidal particles, because living functions can not be manifested by gases and liquids.

The poison of smallpox being thus animate and particulate is generated exclusively in the bodies of men and women. It is probably thrown off from all the eliminating surfaces of the smallpox patients. It can be carried from place to place and from person to person, on the point of a lancet, in bedding and clothing, by cats and dogs, and perhaps by flies. It is doubtless carried through the air for short distances; but it is important to remember that it will not ordinarily cross a street unless it is carried by some human or animal agency. If it invades the premises of your next door neighbor you can close the windows on that side of the house and sleep in peace.

How the smallpox poison finds its way into the bodies of its victims is a question of curious interest. It is usually assumed that it is taken in the act of respiration, although we know that the vibrissæ of the nose strain out nearly all the bacteria of inspired air; and that the mucous membrane of the nose is highly antiseptic. I do not know that it has even been supposed to gain entrance by way of the mouth. I should be strongly tempted to believe that it is always introduced through some abrasion by some indirect process of inoculation, but for the fact that the symptoms of inoculated smallpox differ so widely from the symptoms of smallpox contracted in the usual way. At the point of inoculation in inoculated smallpox the papule can be discovered on the third day; the vesicle at the point of inoculation is fully developed on the fifth day, and the eruption over the body is in full bloom on the eighth day. In ordinary smallpox the usual period of incubation is twelve to fourteen days. So the theory of accidental inoculation will not hold good.

The smallpox poison is very easily destroyed. It is killed at a temperature below that of boiling water. It is killed by the fumes of sulphur. It soon disappears by exposure to sunshine and fresh air. In spite of all the books say to the contrary, it shows far less disposition to spread in warm weather than in cold weather. In our long southern summers on the Gulf coast it almost dies out, even when no effort is made to prevent its spread. It affects the negroes much more severely than it does the white people.

In passing through the body of the cow the virulence of smallpox is greatly modified, so that cowpox is a very much milder disease than smallpox. Vaccinia, the product in the human subject of inoculation by the virus of cowpox, is a mild disease, and affords protection against ordinary smallpox. This is the discovery of Jenner which we celebrate to-day, and furnishes us with an easy transition from problems in smallpox to problems in vaccination.

As of the virus of smallpox so of the virus of vaccinia: we know but little of its physical and vital composition. For the same reasons as those mentioned in the discussion of the virus of smallpox we know that the active agent in the virus of vaccinia is a living colloidal, particulate organism. Ernst and Martin, of Boston, are reported to have found in vaccine lymph a micrococcus which can be separately obtained, and which when inoculated in calves and children will produce the characteristic vesical. I know nothing of the details of their research. The almost forgotten researches of Chauveau in 1865 to determine the infectious principle of vaccine lymph, are perhaps still of some value. He found vaccine lymph to be composed of a fluid part, in which were white blood corpuscles, and a number of granules many times smaller than the leucocytes. These constituents were separated by a process of diffusion and it was shown that on inoculation it was the granules and the granules alone that communicated vaccinia. Chauveau's conclusions seem to have received confirmation from similar experiments made by Ferdinand Cohn and Burdon-Sanderson. Cohn even asserted that those micrococci could be cultivated outside human and animal bodies.

Smallpox may be prevented from spreading by the intelligent interposition of isolation and disinfection. But of all the prophylactic measures which have ever been made use of against smallpox vaccination is by common consent the most important. When Jenner had succeeded in demonstrating his discovery, it was confidently predicted that the reign of smallpox would be speedily ended, and the world permanently freed from the immeasurable evils which during many centuries it had inflicted on the human family. Very vigorous efforts were employed by the medical profession to extend the practice of vaccination amongst the people generally; and in many, perhaps in most, European countries it has been made obligatory by express provision of law. The results have not been altogether in harmony with the anticipations of its advocates. It is true that the prevalence of smallpox has been greatly diminished; and it is true that the percentage of smallpox mortality to population has exhibited much lower averages since the introduction of vaccination than before; so that there can be no question that it has been the means of saving the lives of many thousands, I might perhaps safely say, of many millions of human beings. Saving so many lives I have said; I should have been more accurate if I had said, prolonged so many lives; for of course finally all of them have to die.

But notwithstanding all this, the dreadful malady which had been so confidently consigned to extermination, has still managed to maintain a tolerably vigorous existence among the nations. Now that the conditions of the problem are better understood we are obliged to conclude that the final extinction of smallpox will not be accomplished until our civilization obtains a much higher grade of development than any

which it now presents, or which it is likely to reach for some centuries to come. The reason for this conclusion is easily found. It is not that our medical ancestors were greatly mistaken in their estimate of the protective value of vaccination; but that the experience of a century has shown that under existing circumstances it is practically impossible to secure the thorough vaccination of the whole population of cities and states.

And yet the prophylactic efficacy of vaccination has been and is now to some extent over-estimated, because a great many physicians do not sufficiently appreciate that in very many cases the temporary protection afforded by vaccination is not permanent, does not last for the remainder of life; and because so many vaccinations are inadequately done. A single small vaccine vesicle will protect for a time. But several vesicles or a cluster of vesicles will protect for a much longer time.

Then there are a considerable number of our fellow-citizens, who are very earnestly opposed to vaccination. It is true that in this opposition they are most unwise, but even in their folly they are entitled to considerate treatment. Only two or three weeks ago I read in the *ASSOCIATION JOURNAL* that there was then prevalent in Gloucester in England a sweeping epidemic of smallpox due to the resolute refusal of vaccination by an anti-vaccination league. And this in the very county in which Jenner pursued his investigations. Compulsory vaccination laws inevitably lead to anti-vaccination leagues.

I am myself opposed to compulsory vaccination laws. I think they trench too much on the liberty of the citizen, and beget a very troublesome opposition from many who would otherwise in case of danger submit to vaccination as a matter of course. I know the argument is that these anti-vaccination cranks imperil the health of communities. Sometimes they do; but communities can protect themselves by isolation and disinfection—in a word, by quarantine against the few dangerous persons who would hold out against vaccination in emergencies; and if any of my fellow-citizens insist on running the chances of dying from smallpox I would be the last man to deprive them of that privilege.

Much has been written as to the comparative merits of humanized and bovine vaccine. It is the fashion just now to prefer the bovine virus, and I in practice follow the fashion. We do not have much smallpox in Alabama and consequently we do not need much vaccine. When we do need it it is convenient to order the bovine article, and we do so. But I am profoundly satisfied from a very large experience that the humanized virus, in the form of lymph or of crust, has equal prophylactic power, is equally safe from unfavorable complications, and is followed by a smaller percentage of bad arms. The enthusiasm for the bovine virus has been largely manufactured to order by the managers of vaccine farms. Jenner used the humanized virus, and Jenner's successors for two generations used the humanized virus. The common use of the bovine virus has grown up during the last thirty years.

The communication of syphilis along with the vaccine is the complication that has been specially dreaded. I know the famous cases related by Mr. Jonathan Hutchinson, and by Mr. Thomas Smith. I know nothing about Mr. Smith, but I do know that Mr. Hutchinson was always seeing a lot of things

that were not obvious to anybody else; and I remain very incredulous about vaccinal syphilis. In Mobile in 1874, some twelve thousand vaccinations were done with the humanized lymph, and I never heard of a case of vaccinal syphilis.

The vaccine vesicle is a living thing—a growth as much as cancer or tubercle is a growth, and the presumption is that in the process of growth it converts everything which it appropriates into its own nature, and this without regard to the soil in which it grows. Just as, for illustration, the poisonous night-shade, the delicious strawberry, and the medicinal poppy, may all grow side by side, out of the same soil, and be fed with the same food, and yet each remaining true to its own special nature, will produce its own characteristic fruit.

The location of the vesicle is among the epithelial elements of the derma. The epithelial cells take part in the growth of the vesicle, and it is through their agency that it becomes many chambered. The chambers are filled with transparent lymph. It never passes through a pustular stage. In about eight days it attains its full development, after which the lymph gradually concretes into a crust which is firm and tough and translucent like horn. The color is sometimes a light amber, sometimes a deep amber, sometimes a dark mahogany, and sometimes almost an ebony black, depending always on the color of the skin on which it grew. The darker the skin the darker the crust. The color is due to the pigment cells which remain entangled in the crust when it dries.

I hope I may be excused for speaking at so much length. Gentlemen, I thank you for your kind attention.

CLINICAL MEMORANDA.

Read before the Chicago Pathological Society, April 13, 1896.

BY ARTHUR R. EDWARDS, M.D.

Professor Therapeutics Northwestern University Medical School;
Attending Physician Cook County Hospital; Pathologist to
Cook County, St. Luke's and Wesley Hospitals.

I. CASE OF CIRRHOSIS OF LIVER WITH PRE-ASCITIC EDEMA OF LOWER EXTREMITIES.

J. A. N., a laborer, married, 43 years old, American; under observation from Jan. 25 to Feb. 6, 1895. By occupation he was an engineer. His affection began two weeks before entrance, with an initial chill, with pains over the entire body, in every joint and in the head. He had during this period suffered from hourly vomiting, and frequent diarrhea. The bowels had been usually constipated. Hiccough had troubled him excessively. His wife stated that the patient's illness began suddenly with involuntary evacuations from the bladder and rectum, accompanied by an enormous appetite and thirst. His left arm had been limp and painful for some time past. The lower extremities, together with the other parts, have grown emaciated till some six days since, when considerable anasarca about the legs and ankles developed. He had always lived in this State. He married a year ago. His wife noticed large veins in the legs, but had never seen any upon the abdomen.

Examination: Involuntary urinary and fecal evacuations existed with retention of urine, 4,100 c.cm. of urine being withdrawn at one time. The urine contained no albumin nor sugar, was neutral, sp. gr. 1.013, 2.3 per cent. urea, no pus nor casts in the sediment. Respirations varied from 18 to 20, the pulse

from 80 to 90, and the temperature from 98 to 101 in axilla. He vomited frequently. Rectal examination was negative. Upon the trunk and lower extremities appeared an eruption of erythema nodosum, upon which basis bullæ later developed. His legs and feet were much swollen. Upon both legs and over both inguinal and hypochondriac regions were observed very large, extremely tortuous veins. The eyes and discs were negative. The blood examination showed no changes in stained specimens. Sordes existed upon teeth and lips. The lymphatic system, the bones and muscles were negative. The heart was not enlarged in any direction, the first tone over the apex being weak, and the second aortic tone was considerably accentuated and transmitted into the cervical vessels. No murmurs were obtained. The radials were not hard and the pulse was 90, regular and compressible. Marked pulsation existed in the jugulum and supra- and infra-clavicular regions. The second pulmonic tone was questionably accentuated. The lungs were tympanitic laterally and anteriorly, no râles were heard in front, respiratory excursion was demonstrated on both sides, although it was hard to get the patient to breathe deeply. Over the lower lobes behind, hypostasis was diagnosed from the presence of inspiratory râles and relative dullness. The liver on percussion lay within the usual limits, except that tympany existed over the location of the entire left lobe. The spleen was indeterminate on palpation. No free fluid was found in the peritoneal cavity. Rectal examination was negative. The umbilicus presented no changes. There was no icterus. Marked delirium, slight cyanosis toward the end, emaciation, and a subnormal and even collapse temperature were noted. The genitalia were hyperemic and slightly eroded by the ammoniacal urine.

The prognosis from the first was absolutely unfavorable, and the therapy of free stimulation, alcohol and supporting measures were wholly unavailing. The case is, therefore, presented wholly for its diagnostic and pathologic phases.

Diagnosis: An arterio-sclerosis with secondary cardiac hypertrophy having been diagnosed, there was still an underlying disease which threatened life. The findings were few and the chief interest centered in the greatly dilated veins in the abdomen and legs, which obviously indicated obstruction. The argument, diagnostic and pathologic, was to my mind most interesting. Was the obstruction intra-thoracic? The venous ectasia was rather too low to favor this construction. Was then the return venous flow impeded in the vena cava or in the portal vein district? No cause could be invoked for the theory that the cava was compressed; there was no tumor, no inflammatory focus, etc., hence attention was directed to the liver. There was no real jaundice, no ascites and no splenic tumor; yet knowing that a free collateral circulation may prevent or succeed in time a hepatic cirrhosis, and that the passive congestion of cirrhosis may in exceptional instances antedate the ascites, the antemortem diagnosis of hepatic cirrhosis was made (in the presence of the late Dr. D. D. Bishop, Dr. Stout, Dr. Skinner and Dr. Hardie).

The necropsy findings were in brief: Kidneys, 10 x 6 x 3.5 cm., 10 x 6 x 3 cm., 300 gm.; surface slightly roughened; capsule freely separable; showing no marked naked-eye changes; microscopically, some slight arterial alterations and inconsiderable islets of connective tissue change were observed. The heart

weighed 420 gm.; the left ventricle was 20 mm. thick and the aorta was somewhat atheromatous. Lungs: Some few adhesions in the right pleura; moderate marginal emphysema; mechanical hypostasis. Spleen: 170 gm.; very marked perisplenic changes, explaining the inconsiderable size of the organ compared with liver. Liver changes: 28 x 18 x 18; 5 x 8 x 6 cm., 2,000 gms.; surface smooth, no adhesions; porta free; the organ was universally red; the lobules were centrally fatty and in their periphery exhibited delicate strands of connective tissue. Microscopic examination revealed a typical fatty alcoholic cirrhosis without any striking anomalies. The gastro-intestinal tract was negative. The peripheral veins conformed to the clinical signs. The vena cava was not compressed, not involved in any cicatrix, not the seat of any thrombosis, etc. The subperitoneal veins, especially in the right inguinal region, were varicose even to bursting. The clinical diagnosis of a latent hepatic cirrhosis, with collateral circulation sufficient to obviate ascites and splenic tumor, was confirmed.

Labadie-Lagrave states that pre-ascitic edema of the lower extremities may appear as an initial or as an almost isolated symptom of cirrhosis. It was first described by MacSweeney in 1876, then by Giovanni, by A. Gilbert and H. Presle (*Thèse de Paris*, 1892). While edema as a rule accompanies or follows the ascites, it may antedate the appearance of ascites by months, even 1½ years. When it accompanies the first cirrhotic symptoms, it is a sign of diagnostic importance.

It may occur not from portal vein stasis alone but from cicatrices around the cava, cachexia, heart or renal complications.

Thierfelder believes the occasionally earlier appearance of anasarca before ascites is often more apparent than real, since edema is better seen by patient and physician alike. Such edema may be due to meteorism or fluid pressing upon the cava or iliac veins. Bamberger explained edema of the lower extremities in isolated cases by the fact that the pars hepatica of the cava inferior suffered contraction by shrinking of the cirrhotic liver.

However, I am convinced that none of the enumerated causes operated in this concrete instance. The great collateral circulation opened channels of communication between the vena porta and venæ epigastriæ, by means of which the blood flows from the latter to the venæ crurales and produces an edema of the lower extremities before a great degree of ascites is present. Monneret has described an instance in which, by the mechanism suggested, the overfilled epigastric veins produced edema of the abdominal walls.

II. CASE OF ASCITES CHYLOSUS.

The following case entered the service of my friend Dr. Worthington, by whose courtesy and that of Dr. F. A. Besley, I was enabled to study the case clinically and report it. I performed the postmortem in the presence of Drs. Worthington, Besley, Olney, Wood and Richter.

The case presented no remarkable clinical features but details are in place because of the rarity of the complicating chylous ascites.¹ The patient aged 32, married, of American descent, barber by trade. Under observation two months. The family history was negative beyond the death of a sister from gastric

¹ Edwards, *Ascites chylous s. adiposus*, "Medicine," August 1895.

tumor. The patient had a diarrhea for past seven or eight years which recurred several times a year, each time lasting three or four weeks, amenable to careful dieting. Three weeks before entrance, he had a severe chill with fever and suffered severe pain in the left side. He coughed and expectorated freely. No hemoptysis.

Physical Examination: Mind clear; eyes negative; tongue coated but moist; pharynx, ears, scalp, calvarium negative. Lungs: On both sides there was flatness below, reaching as high up in axilla as level of nipples; there was also absent or greatly diminished breath sounds, greatly decreased vocal fremitus, distant crepitant and subcrepitant râles; at level of flatness was bronchophony and above it were an increased percussion note, exaggerated breathing and a few râles. No respiratory excursion existed on either side. Cardiac percussion gave a triangular shaped area of dullness, with its apex directed upward, its sides, which diverged downward, passing wide of the sternal margins and fusing with the dull areas on either side. Over the basis was heard a to-and-fro murmur which was simplified into a systolic murmur at the apex. The murmur was a typical friction rub. The cardiac action was visible only in the second and third left intercostal spaces. While the pulse was full yet the heart tones were very distant. The liver dullness merged with that of the lungs, indefinable above but reaching three inches below the normal lower limit of hepatic dullness. Spleen not palpable. Great abdominal meteorism, but fluid could not be positively affirmed, although considerable effort was made to find it, since the abdomen was prominent. One week prior to death, free fluid was demonstrated in the peritoneal cavity. The pleural cavities were each tapped three times, and clear yellow serous fluid of sp. gr. 1013 was obtained. The pericardial sac was also tapped in the fourth left intercostal space, and a sero-sanguineous fluid withdrawn with a sp. gr. of 1021. The temperature curve was irregular, remittent in type, with apyretic intervals of variable duration. The pulse was uniformly high, as was also the respiration rate. The patient was treated with guaiacol, malt and cod liver oil, and later, whisky, strychnia and digitalis were added. Diuretic and potas. acetate were also employed as diuretics. The urine was negative. The clinical diagnosis was: 1. Effusive pericarditis, probably tubercular from the hemorrhagic character of the exudate and the cachectic condition of the patient. 2. Pulmonary compression from double hydrothorax (no bacilli were found clinically). 3. Liver of passive congestion. 4. Hypostatic edema and ascites. The clinical diagnosis was confirmed in every respect except regarding the interpretation given the ascitic fluid which was chylous and not purely serous.

Postmortem five days after death: Slight post-mortem lividity; no rigor mortis; nourishment fair; pericardium contained three ounces of a bloody serous fluid; the two layers were covered with shaggy fibrinous flakes; both leaves of pericardium were rough and, where not rough, edematous; the exudate was one-fourth to one-half inch thick over the heart. The endocardium was wholly negative, both parietal and valvular. More careful examination of the deeper layers of the exudate revealed innumerable small tubercles, and upon the diaphragmatic surface of the pericardium was a large solitary tuber-

cle as large as a walnut. The myocardium was pale, firm and, nearest the pericardium, edematous.

The peritoneal cavity was full of a malodorous, milky fluid which contained some few yellow flakes. The peritoneum was smooth and glistening throughout its entire parietal and visceral expanse. Stomach and intestines negative. Diaphragm reached to the sixth rib on the right side and to the eighth on the left. Appendix free from adhesions. The liver was fully a hand's breadth below the costal arch; its edge was rounded and its markings fairly distinct. In the left pleural cavity were some few firm adhesions with an eruption of miliary tubercles on the diaphragm. The right lung was free, crepitated feebly above and the lower lobe was devoid of air. Firm adhesions over left upper lobe, lung crepitates feebly, lower lobe airless. Spleen 18 x 4 x 15, soft, flabby, friable. Kidneys, dark in color; capsule peels readily; cortical markings distinct.

Anatomic diagnosis: Chylous ascites; hydrothorax and pleuritis; pericarditis effusiva tuberculosa; parenchymatous degeneration in the liver and kidneys; splenic tumor.

I have lately misplaced the record of the chemic analysis, but fat was present in traces. There was a very slight but distinct sugar reaction, while albumin was present. Microscopically, the fluid was teeming with bacteria on account of the late date of the autopsy and leucocytes bearing granules were sparsely scattered through the sediment, together with amorphous granular masses. The case must then be included in the class of chylous ascites, the number of which is very small, since scarcely a dozen cases are recorded in which sugar was found. Cases of chylous ascites are indisputable when 1, macroscopic rupture of the chylous tracts, 2, microscopic rupture of the same are demonstrated, and 3, when sugar is found. In the genuine chylous ascites, rupture may occur anywhere in the chyle system. The return chylous flow may obstruct anywhere from the smallest to the largest vessels.

However, in the case reported no such rupture nor obstruction could be demonstrated, if we except the obvious impediment to the chyle and vascular flow, the pericarditis and the myocardial inadequacy. The presence of sugar, when diabetes is excluded, is proof positive of chylous ascites.

Our explanation of the chylous effusion is the following: The cardiac power was reduced by the infiltration of the myocardium, per contiguitatem, from the inflamed pericardium. As evidence, we note the edematous subpericardial portion of the heart's musculature. A second cause of reduction in the heart's efficiency resides in the compression of the viscus by the pericardial exudate, which explains the pallor of the myocardium on section. The cardiac obstruction was reflected peripherally into the venous system, hence the synchronous cessation of the normal centripetal chyle flow. Serious stasis in the distal chyle vessels resulted with final attenuation and rupture of their walls.

It is highly probable that the ascites was primarily serous and became only later chylous. There are some seven instances of this transition on record. The nature of the fluid was in this, as in other instances, a postmortem surprise, but never has chylous ascites been diagnosed before death or paracentesis, since there are no infallible, nor indeed even highly suggestive, diagnostic signs. Its proper recognition

would have necessitated a prognosis even graver than that of a tubercular pericarditis, but it could in no wise have had any therapeutic value.

103 State Street.

DISCUSSION.

DR. HERRICK—I should like to ask Dr. Edwards if there is not but one other case or at least very few cases in which cardiac obstruction has produced chylous ascites?

DR. EDWARDS—I think there are more than that. Dr. Busey, of Washington, wrote an article on the subject in which he thought there were a number of cases where, for instance, a tricuspid lesion or a secondary endocardial lesion, or even a lung obstruction which would affect the right heart caused chylous ascites; but they are relatively few, and I think there were only three authors, Niemeyer, Busey and one other who called attention to that point.

DR. BURGESS—I will confine myself to the description of a case of cirrhosis of the liver which I have recently seen, which also had unusual vascular disturbances of the liver itself. I never saw the patient during life, but I understand that the first that was known of him was that he had some attack of heart trouble and an examination revealed that he had a myocardial lesion and also had a systolic venous pulse; at this time there was some anasarca, and the liver dullness in the vertical direction was much increased, about six inches, and on depressing the abdominal wall the liver could be taken in the hand and pulsation felt. Care was taken to exclude all communicated pulsation, and the diagnosis was that there was a pulsation in the liver itself, in the substance of the liver. The case went on and finally a great deal of ascites developed, and that is about all I remember of the clinical history. At the autopsy the liver was found in an advanced state of cirrhosis. It was smaller than normal; the well-known ax-shaped liver was present. The condition of the heart was, that there was a competent pulmonary and aortic valve, with incompetency of the tricuspid and mitral valves; the ascending vena cava was very much widened; the veins which empty from the liver were very much widened and in passing a stream of water from the tap into the liver it could be seen distinctly to swell out, and then on squeezing out the water, which was not a great amount, and repeating the process the same thing happened over again: so in this case the pulsation of the liver was marked enough to be well felt, and of course was due to the pulse of the right ventricle going through the tricuspid, which was incompetent.

ANTITOXIN IN THE TREATMENT OF DIPHTHERIA.

WITH REPORT OF FATAL TERMINATION OF CASE AFTER RECEIVING PROPHYLACTIC DOSE.

Read before the Ohio Medical Society at the Fifty-first Annual Convention, May 28, 1896.

BY S. S. HALDERMAN, M.D.

PORTSMOUTH, OHIO.

A death occurring in about four minutes after injecting under the right scapula, in a boy five years old, a prophylactic dose of Behring's antitoxin, No. 0, furnished the excuse for this paper.

I have had an experience of eight months in the treatment of diphtheria with Behring's remedy, embracing the administration of the remedy to seventy cases of the disease, several of them bacteriologically examined, and all presenting the usual well-marked signs and symptoms of the disease, and occurring during an epidemic of a severe type of the disease, characterized by a high rate of mortality where antitoxin was not employed in the treatment, without losing a case so treated. After having used it for prophylactic purposes in twenty-seven cases that had been directly exposed, and in many of these the exposure was continued, with the desired result in preventing the disease in all but three cases, these three cases manifesting evidence of the disease within less than seventy hours, showing that it was already in their systems and incubating. I felt justified in the use of the pre-

ventive remedy in this case. Seven children were in the family, the oldest less than 11 years, the two youngest five months old; they had commingled freely with the affected children, and that those not affected, five in number, would have diphtheria seemed to all concerned very evident.

After having treated the two oldest children, aged respectively 8 and 10 years, to the satisfaction of the parents, who had previous unpleasant experience in the deaths of two relatives, children, both occurring in one day, I did not feel justified in withholding their importunities to use the remedy to prevent, if possible, the dread disease in the other children.

I had given the prophylactic dose, Behring's No. 0, to Seva, aged 2½ years. Willie, aged 5 years, was awakened from a sound sleep, and the dose, No. 0, operation No. 161, was injected just below the right scapula in the tissues underlying the skin; he made but slight outcry, lay down and was noticed to try to scratch the seat of the injection. I walked across the room to a table and washed my syringe, which consisted of an ordinary barrel and piston made for the purpose, and capable of holding about 30 c.cm. After having washed it in hot water I took the cork from another bottle, No. 0, which, as you are all doubtless aware, consists in quantity of about 2 c.cm. of the serum, took this up into the syringe, and proceeded to administer it to George, aged 6 years. While I was making this injection the mother's attention was attracted to Willie by some struggle on his part, and she immediately called to me that something was wrong. I looked and observed a striking cyanotic appearance of skin of face, puffing, swollen appearance of lips; with the finger I could detect no radial pulse; ear to region of heart revealed the absence of the faintest sound from that organ. A resort was immediately had to artificial respiration, while the parents were directed to procure a syringe and inject some whisky per rectum. Twenty-five minutes' effort at restoration was of no avail. It is my opinion the heart never pulsated after somewhat less than four minutes from the time he got the injection.

As to the cause of the fatal result, it is not clear to my mind. The suggestion of a fellow practitioner seems reasonable, and I can do no better than give his words. "It was one of those peculiar idiosyncrasies that sometimes we meet with, obnoxious to agencies and influences that do not affect the general class, and that we can not guard against because of their infrequency and negative indication." We meet with such now and then when exhibiting anesthetics and other agents, and even in the cases of the disagreements of some kinds of food (not ptomaines) which seem to act as poisons, such as oysters and shellfish of any kind, likewise eggs and milk. You have all met with these peculiarities.

The wide adoption of antitoxin as a remedy in diphtheria enables one to draw some useful conclusions as to its value. Yet I speak with some caution and reserve with my limited experience of the remedy, and the results in my own practice have led me to wonder if it were really the treatment with antitoxin or the non-employment of remedies, such as chlorate of potassium, internally, and local irritants to the diseased parts, that had something to do with the uniform and rapid recovery of my cases. Drs. Hare, Smith and others have advised against the internal administration of chlorate of potassium in the disease, because of its possible damaging effects

on the kidneys; yet it is not an uncommon thing to see prescriptions containing a saturated solution with an excess of the salt; the patient directed to take a teaspoonful of this mixture every one, two or three hours. The question very naturally arises, how many cases of fatal kidney disease might not have occurred had chlorate of potassium not been employed. I have not given a grain of the salt in diphtheria for many years, and since the adoption of antitoxin have given but few drugs. Usually in conjunction with the injection of antitoxin I would give calomel pretty freely for its cathartic effect, advise the free administration of beef tea, sterilized milk, coffee, and if the patient desired any carefully prepared food, and give a prescription combining a few drops of tr. ferri chlorid. in glycerin and syrup, to be given hourly, more to occupy the mind of the nurse than for any other purpose. If there was great restlessness, small doses of chloral and morphia to procure the desired sleep, as you are aware nearly all cases of diphtheria are attended with considerable restlessness. After exfoliation of membrane and subsidence of fever, I would give small doses of quinia and strychnia; quinia sulph. gr. xv; liq. strychnia acetat. (Hall's) 3i; yerbazin (Lilly) 3iii. M. Sig.: Half teaspoonful every four hours to child one year old, and order its continuance for not less than three or four weeks. Of the various local applications administered I think most of that of Loeffler, and in young children I have diluted the solution with alcohol and water, and directed that the mouth be swabbed out occasionally with this preparation. In the case of older children and adults, would advise the use of the solution in full strength. The preparation consists of menthol, 2½ drams dissolved in 9 drams of toluol, 1 dram liq. ferri chlorid., and alcohol, 2 ounces.

Of the seventy cases of diphtheria treated by the writer, abscess did not occur in any, of cutaneous manifestations one, a slight urticaria occurring fourteen days after injecting a girl, aged 8 years, with Behring's antitoxin No. 2. This patient had also some slight manifestation of articular trouble in left hip, but the mother, a very intelligent lady, said the child had previous to her illness from diphtheria frequently complained of joint pains, and she thought her rheumatic. Diphtheritic paralysis was noted in one case, was of short duration; in this child there was irregular heart action occurring at the same time of paralysis, about twelve days after receiving the antitoxin. Albuminuria was noted in five cases; one of these was a case of diphtheria supervening upon measles; a boy five years old had a severe case of measles, and on the eighth day of that disease was attacked with croup, which was proven diphtheritic bacteriologically.

There was abundant evidence that the formation of the false membrane was checked; that its exfoliation was hastened, that the throat was free from membrane earlier than in cases not treated with antitoxin. It was clearly apparent from all the manifestations that the toxemia was relieved and lessened. The health officer's record shows that cases treated with antitoxin were discharged convalescent in average of less than seven days while those treated with other methods had an average of ten days. Of five cases having the appearance of being mild, treated by the writer without antitoxin, two died. Of the three recoveries, one was unable to walk from September 20 to November 11, another was feeble for some weeks in spite of

careful nursing and continued administration of tonic remedies. One of these cases was so mild in appearance that the mother protested against the use of antitoxin, said she would not believe the child was sick if she did not see the swollen glands and exudation in throat. This child died ten days after the invasion of the disease from laryngeal stenosis, expired within half hour after symptoms of croup.

Experience and statistics all show the importance of early treatment by serum, mortality increasing with the days of the disease before treatment. Under the influence of early serum treatment the disease loses its progressive character and this is true in regard to laryngo-stenosis. Of the seventy cases there was but one instance in which laryngo-stenosis symptoms developed. In many cases of very active glandular inflammation with abundant formation of membrane, the effects of the treatment were very striking. Within thirty-six hours in some of the most severe cases there was marked improvement in the general condition, improvement of pulse, fall of temperature and considerable, if not complete, exfoliation of membrane.

The limitation of time makes it impossible to discuss the position of antitoxin treatment of diphtheria fully, and I will not consume the time of this Convention with statistics, but will conclude by saying that in my opinion all patients are benefited by the treatment when administered in time to accomplish any results with a reasonable hope of recovery. The administration of antitoxin does away with the necessity for any other but the use of local disinfectants to prevent or limit the growth of bacteria in the throat and supporting treatment.

DISEASES OF THE LACHRYMAL GLANDS.

Read before the Nebraska State Medical Society at Lincoln, May, 1896.

BY H. S. BELL, M.D.

KEARNEY, NEB.

Diseases of the lachrymal passages are frequently brought to the attention of the general practitioner, and I am inclined to believe that our substantial knowledge of the causation, course and treatment of these diseases is not as full and practical as it should be.

The reason for this scant information can not be explained by the relative infrequency of this class of cases, but mostly from the comparatively little attention writers and teachers have heretofore given this subject. Believing this, I have thought I could best serve this society by a discussion of this very common, but too much neglected class of diseases.

The diseases which most frequently affect the lachrymal passages, are those involving the ducts leading from the eye. Near the inner canthus of each eye there may be found two small openings, one in the upper and one in the lower lid, called puncta. These are the orifices of the canaliculi, two very small canals leading into the lachrymal sac, which is the upper dilated end of the nasal duct. In this expanded pouch, or lachrymal sac, is the most common seat of disease, and from this vulnerable point the trouble is liable to involve either the nasal duct or the canaliculi or both.

The nature of the diseases affecting these passages is mucous and purulent inflammation. The most common form is a catarrhal inflammation of the lachrymal sac and its ducts, the most prominent symptom of which is an overflow of tears, and it is for the relief of this symptom the patient first seeks advice.

The tears accumulate in the lachrymal sac and distend it in such a manner that it stands out from the side of the nose as a distinct prominence, and for the relief of this fullness the patient is obliged to empty it several times a day by pressing it with the finger in an upward and inward direction. This pressure will often cause the watery secretion to be discharged in a continuous stream as if from a hypodermic needle. If the conditions upon which this catarrhal form of the disease depend are not relieved, it will finally result in what is termed "blennorrhea" or mucocoele, which is characterized by a mucous or gelatinous discharge, which the patient presses out with the finger. Dacryocystitis is an acute purulent inflammation of the lachrymal sac, and the skin and cellular tissue just below the inner canthus of the eye becomes swollen, red and tender to pressure; in fact, the symptoms of a localized cellulitis with abscess. This acute form of the disease is not so common as the catarrhal variety, and requires prompt treatment to prevent a fistulous opening in the lachrymal sac. It is refreshing to find such a unanimity of opinion as to the causation of these lachrymo-nasal affections. It is fully agreed that they have their starting place in subacute or chronic coryza. In fact, chronic rhinitis is said to be not only the cause of all the affections of the lachrymal ducts, but to be the prolific source of most all the inflammations of the ocular and palpebral conjunctiva. Dr. Ziegler, of Philadelphia, in the *New York Medical Journal* of Nov. 3, 1894, says: "I think we may safely say that fully 90 per cent. of corneal lesions take their origin directly from preëxistent pathologic processes affecting the intranasal tissues and secretions."

Dr. Woodruff, of Auburn, N. Y., in the *Medical Record* of April 25, 1896, in a résumé of a recent work by Dr. Finck, of Hamburg, Germany, says: "Not a few affections of children can be traced back to a chronic coryza." "Zieme even asserts that two-thirds of all eye diseases are due to nasal affections." "Von Hasner found that among fifty-nine cases of diseases of the lachrymal duct, fifty-one showed a pathologic condition of the nasal cavities." J. Michel and Seifert observed among thirty-eight cases of dacryoblennorrhea, thirty-seven with affections of the nose. Farravelli and Kruch found among cases of diseases of the lachrymal sac, thirty showing nasal catarrh. The consensus of opinion is overwhelming that lachrymal and ophthalmic diseases have their origin in the catarrhal inflammations of the nasal turbinates. From what has been said of the causation of diseases of lachrymal apparatus, it would seem the treatment would be exceedingly simplified, and should be directed to the existing coryza. This is the logical conclusion and the natural key to the successful and intelligent treatment of this class of affections. Expediency, however, will sometimes control in the decision upon a given line of attack. Little children, in whom these diseases mostly abound, are naturally timid and impulsively shrink from the attentions of those with whom they are unfamiliar. They will not even permit their parents to use the simple means of treating these nasal inflammations. After having fully posted myself on the etiology and pathology of these lachrymo-nasal diseases, and lamenting the difficulties with which I was handicapped in conducting their logical treatment, I read a paper by Dr. P. Richard Taylor, Louisville, Ky., in the issue of Jan. 1, 1896, of the *JOURNAL*, where he advocated the use of a tube

which he designed for the treatment of these lachrymal duct diseases. I had previously read in the *Medical Record* of June 1, 1895, of "A Simple and Effective Method of Keeping the Obstructed Lachrymal Duct Open," and which was said to be a "trick" worth knowing. This method by Dr. Walter N. Vilas, of El Paso, Texas, consisted in passing a small-sized probe armed with a canula through the nasal duct, then the probe is withdrawn and through the canula is passed a silkworm gut suture, the lower end of which is brought out through the nose and a split shot is clamped upon it. The canula is now withdrawn, and the silkworm gut ligature is drawn up until its further progress is arrested by the shot within the nose, when another shot of lead or aluminum is clamped upon the strand of gut as it emerges from the inner canthus of the eye. It was said in the article referred to that this method had been tried in a number of cases of lachrymal obstruction and abscess of the lachrymal sac with unfailing success and commends itself for its simplicity, practicability and radical effectiveness, as well as the important consideration of abridging the treatment of these cases to one sitting.

Dr. Taylor's "tube is seven-eighths of an inch long and three-eighths inch angle, and can be made of any size and of any metal. It has a lateral slit on both sides of the short end, leaving a duckbill snout with upper and lower blades, both of which are to be beneath the surface of the lids or entirely in the passage and hidden from view. The slit prevents the soft tissues from closing the opening of the tube or hindering the passage of the tears through the tube." Each of these methods is designed to effect a cure by drainage. I had about made up my mind to try the plan, but in the meantime the method of Dr. Taylor engaged my attention and appealed to my judgment as being the best. Having three patients with obstruction of the nasal duct with the prominent symptom of weeping eye, I ordered three of Dr. Taylor's tubes. Two of my patients were children under 5 years of age. One of these, a little girl, had had frequent attacks of dacryocystitis, which had resulted in openings from the lachrymal sac through the skin just below the inner canthus. From these fistulous tracts pus and tears were constantly escaping, producing an ugly eczematous eruption over that portion of the cheek. This child was given chloroform, the lower puncta entered by a Weber probe-pointed canaliculus knife, the canal was slit into the lachrymal sac, when, with Bowman's set of probes, the nasal duct was rapidly dilated and this tube, which was introduced in January last, was inserted. I removed it a few days ago for the purpose of exhibiting it to this society to-day. I shall, upon my return home, reintroduce it. The fistulous openings have closed, the eczema disappeared and nothing remains but a faint cicatricial scar. The conjunctivitis with its purulent exudation has also disappeared.

The second case was a child presenting only the catarrhal form of the lachrymal sac with obstruction to the passage of tears through the nasal duct. This child also had chronic conjunctivitis. Prout, of Brooklyn, has described this condition as conjunctivitis lachrymalis, and adds that it can not be cured except by relieving the obstruction to the nasal duct. This child was anesthetized, the lower canaliculus slit into the lachrymal sac, and with the same probe-pointed knife the nasal duct invaded and the stricture cut, after which Bowman's probes were rapidly intro-

duced and a medium-sized tube inserted. After some weeks I decided that the angle of the tube was too long, as it rubbed the eyeball and increased the conjunctivitis. The child was again given an anesthetic, the tube removed and about one-half the short arm of the tube was cut off, and again introduced. This was two months ago. The eye symptoms rapidly disappeared, as well as the overflow of tears.

My third case was a young man 23 years old with mucocoele of the sac of twelve years' standing. In February of this year, with local cocain anesthesia, I did the same operation with the best result.

EMPHYEMA OF ANTRUM SIMULATING CARIES OF TEETH; AND A SIMPLE METHOD OF TRANSILLU- MINATION.

BY HENRY G. OHLS, M.D.

CHICAGO.

About one year ago I had occasion to examine an antrum, in a case where severe pains in the distribution of the right facial nerve, with tenderness over the malar prominence indicated the probability of empyema. The classical symptom of pus escaping from the hiatus semilunaris and visible on the outer surface and lower edge of the middle turbinated was lacking. A competent dentist had diagnosed an inflammation of the dental nerves of the first and second right upper molars and had made several applications through the root canals to destroy the nerves. Failing at last to relieve the pain in that way, the first molar was extracted and after a few days more of treatment and terrific pain, the second molar also was extracted with a large root abscess. Passing a strong curved probe into the antrum through the socket of the tooth, gave vent to about two drachms of thick pus and was soon followed by relief from pain that had been agonizing most of the time for three weeks.

On the evening before the last extraction, I suspected the presence of pus in the antrum on account of the great swelling of the middle and lower tubinated, which might be sufficient to prevent any pus escaping into the middle meatus. I thereupon attempted to transilluminate with Ingals' incandescent lamp, but found that the battery was too far exhausted to give the necessary current. Sufficient current remained, however, to heat the ordinary cautery electrodes and I used a coil of platinum wire, guarding it by a test-tube with a cork cut in two and the halves hollowed out to receive the wires of the electrode. Since then I have used the electrode guarded by a plain two-dram homeopathic vial with entire satisfaction. The vial can be held by the neck between the patient's lips so that the cork prevents any light escaping to confuse the operator. The only mishap I have experienced in a number of trials is the minor one of melting my coil, which can easily be avoided by interrupting the current every few seconds just before the melting point is reached. If the electrode is made of tubing with a coil of platinum wire that slips into the end of the tubes, the coil can be very readily replaced at the expense of a few cents. The current should be slightly greater than that used for cauterization, but can readily be obtained from any cautery battery by cutting out a little more resistance. By covering the vial with opaque paper except at the

end and applying the end to the orbital surface of the frontal ridge some illumination of the normal frontal sinus can be obtained in subjects with prominent ridges. I think some assistance in the diagnosis of frontal empyema may be expected from this procedure, though I have not obtained very satisfactory results. As to the danger of breaking the vial in the mouth, I must confess to feeling some timidity at first, but a large number of trials dispelled this fear. A metal guard would certainly prevent any danger of that kind. Possibly a reflector might be placed beneath the electrode to increase the light, but I have found no case in which the electrode did not furnish ample light. A striking example of the danger in depending on the regular transillumination lamps was read by Jonathan Wright, M.D., before the Laryngologic Section of the Academy of Medicine and reported in the *Brooklyn Medical Journal* of July, 1895. That case presented the classical history and symptoms of empyema of the antrum. Dr. Wright said: "Unfortunately, my transillumination lamp was out

of order, so that I could not apply that test." Upon extracting a diseased tooth and drilling through the floor of antrum no pus was found. "The only conjecture that I could then make was that there was pus in the frontal sinus, but he declined with emphasis the suggestion that he have his frontal sinus opened by external incision. I did not see the patient again, but since then I have not made a diagnosis of antrum trouble without using the transillumination lamp."

Although I have not read of this method being used before I shall be surprised if such a simple procedure has escaped the myriad workers with all the essentials actually in their hands daily. Any suggestion which will give increased usefulness to instruments already in common use for other purposes should be appreciated by physicians, who are so often solicited to buy expensive instruments associated with the names of our inventive confrères, to their advertisement and the financial profit of the instrument maker.

34 Washington Street.

SUBCUTANEOUS INJECTIONS OF SUB- LIMATE AS A CURE FOR CERE- BRO-SPINAL MENINGITIS.

BY J. D. SMITH, M.D.

PADUCAH, KY.

In the *JOURNAL* of Feb. 15, 1896, page 345, quoting from *Sem. Méd.*, Jan. 15, 1896, I find that, "An Italian, Dr. Dazio, suggested the above-named treatment, and with it, Dr. Consalvi, of Casoli, has recently treated successfully nine cases."

I desire to say that I inaugurated a similar treatment at Dyersburg, Tenn., in the spring of 1885.

Having seen as consulting physician, a Mr. McC., of Fowlk's Station, four miles from Dyersburg, in the midst of vigorous manhood, die in great agony with cerebro-spinal meningitis, and two days later a youth of 14 years named Martin, in the town of Dyersburg, sicken and in twenty-four hours die as quietly as one going to sleep; and having practiced through two former epidemics of the disease with little or no

success, I determined on an original heroic course of my own in the event of an epidemic. I had not long to wait. Called next day to see Mrs. H., niece of United States Senator H. from Tennessee, and found her with her head drawn back and in a state of wild delirium. Injected just below the scapula $\frac{1}{4}$ gr. of sublimate and put her on 1-15 gr., with 2 gr. chlorate potass. every hour until the specific effects began to be manifested in alimentary canal. Then I gave same dose at longer intervals. This and some bromid constituted the entire treatment and recovery was perfect.

W. G. B., lawyer, returned from ten miles in the country, where his father had died with the disease, and had a severe attack. He was treated in the same way and had a good recovery.

Lucien S., Deputy United States Marshal, had a severe attack; was treated in same way and made a good recovery.

Thomas T., farmer, six miles in country, took pain in right foot while plowing; pain went to head and he was delirious in two hours; was seen by another physician and given calomel, sulphate magnesia and morphia. He grew constantly worse and when I saw him at the end of eighteen hours from beginning of attack was a raving maniac, with head drawn back almost between the shoulders. Injected sublimate, $\frac{1}{4}$ gr., and repeated in six hours with effect of greatly quieting delirium. He had other small injections and took minute doses by the mouth. This patient remained unconscious fifteen days, but finally recovered with right side partially paralyzed, and after having several abscesses, one of which involved the right testicle.

These were six typical cases of that epidemic, the attacks of the two that died being no more severe than were those of the four who recovered. Together with others they have been reported to the South-western Kentucky Medical Association.

In the winter and spring of 1893, while a severe and widespread epidemic was prevailing in one of the Kentucky counties near Paducah, I treated Mrs. P. and her 10-year-old daughter of Paducah successfully in the same way.

Another typical case that I treated successfully in Paducah at the same time was A. B. A., a young telegraph operator. His case was a severe one which resulted in partial paralysis of the left side, from which he has never fully recovered. Yet he was snatched, as it were, from the very jaws of death by the repeated hypodermic injections of the bichlorid.

A few other cases might be named, but the above are sufficient. Since the adoption of this treatment I have never lost a case of cerebro-spinal meningitis. Before its adoption I lost all. Strange to say, physicians with whom I have conversed about it seem to fear its boldness, and yet they have generally lost all their cases. I try to get the specific effects of the sublimate on the alimentary canal within thirty-six hours and then lighten up my treatment, so as to avoid excessive irritation of the canal. I do this that I may know that my patient has all the sublimate in him that his canal will bear with safety. I sometimes give castor oil and turpentine to clear the canal, bromids to quiet brain action and even give small hypodermics of morphia with the bromid, or bromid and chloral after I get the specific effects of the sublimate. I believe the sublimate destroys the bacteria peculiar

to the disease, just as quinia destroys malaria, and leaves organs already injured by the bacteria in a state of simple inflammation of more or less severity.

SOCIETY PROCEEDINGS

Medical Society of the State of Pennsylvania.

Forty-sixth annual Session of the Medical Society of the State of Pennsylvania, held at Harrisburg, May 19 to 21, 1896.

DR. W. S. FOSTER, of Pittsburg, President. Addresses of welcome were made by Gov. D. H. Hastings and others. The reports of the Secretary showed an increase in membership in many county societies and the addition of four new ones. The reports of the Treasurer and of the Committee on Publication announced an issue of nearly three thousand copies of the Transactions and a balance in the treasury of \$2,500. The Committee on Scientific Business had prepared a program with seventy papers for the meeting. The Committee on Pharmacy urge the need of a closer adherence to the Pharmacopeia and the National Formulary in preference to the prescribing of proprietary preparations. A copy of this report was ordered to be sent to the Pennsylvania Pharmaceutical Association for its next annual session. The report of the Committee on Increase of Membership told of the success of the efforts in that direction, and arrangement for lectures before the county societies to stimulate the attendance at their meetings. The Allegheny County Medical Society invited the State Society to hold its next annual session at Pittsburg. Several amendments to the Constitution of value in order to make the society more effective in its work were offered and laid over for a year.

DR. G. M. BRUMBAUGH, of Washington, D. C., a guest of the society, asked the consideration of certain action now before Congress affecting the work of the Government laboratory at Washington, and a committee was appointed to prepare resolutions on the subject. On motion of Dr. F. LeMoyné, Pittsburg, the following was adopted:

WHEREAS, Contagious and infectious diseases cause a large proportion of the suffering, disability and death of the human race, and

WHEREAS, Such diseases are to a great extent preventable by proper precautions, and

WHEREAS, Tuberculosis, both bovine and human, is known to be contagious,

Resolved, That the Legislature of Pennsylvania is urgently recommended to enact laws by which all centers of population containing 25,000 inhabitants or more be required to provide isolation hospitals with separate wards or buildings for small-pox, diphtheria, scarlatina and erysipelas, and provision should be made for extending the facilities in such hospitals to the surrounding populations geographically and commercially dependant upon them.

Resolved, That laws should be enacted requiring that all cows producing milk should be tested by the most approved methods for tuberculosis at least once in six months, and that all cows found to be tuberculous shall be condemned.

Resolved, That provision should be made for the positive diagnosis of all cases of suspected pulmonary tuberculosis, and that boards of health should be required to enforce adequate precautions against its dissemination.

Resolved, That in consideration of the pernicious character of the water delivered to a large proportion of the people of this country that legislation for the protection of streams from pollution is urgently demanded.

At the afternoon session Dr. C. M. FRANKLIN, Lancaster, delivered the address on "Mental Disorders." It gave a résumé of the improved methods of the care and treatment of the insane, with the causes that have brought about these conditions; the advances and experiments made in pathology and their hopeful tendency; the influence of inebriety, immigration and crime in relation to insanity, with the suggestion that there may be some new legislation giving power to in some way control the extent and increase of the first two and that sociology will teach us to adopt a new condition of things by which the methods of modern life will relieve the undue tension that is at present placed upon the mental faculties.

DR. BUCHANAN, of the special committee on the act before Congress, reported:

WHEREAS, Senate Bill No. 1,552, entitled "A bill for the further prevention of cruelty to animals in the District of Columbia" is pending in the Congress of the United States; and

WHEREAS, We, the Medical Society of the State of Pennsylvania, are fully convinced that this restrictive legislation, should it become a law, would seriously cripple the efforts of the earnest scientific investigators of the District of Columbia (and indirectly of the United States) and would retard the progress of medical science in its beneficent efforts to alleviate suffering and diminish the ravages of disease; and

WHEREAS, Cruelty to animals is not practiced in the District of Columbia by those scientists who unselfishly and with great personal risk strive to increase our knowledge of disease and of the methods of its prevention and cure; therefore, be it

Resolved, That the Medical Society of the State of Pennsylvania hereby urge the Pennsylvania delegation in the Congress of the United States to use all honorable means to defeat the said bill or any similar restrictive measure.

Resolved, That copies of these resolutions, attested by the Secretary of the Medical Society of the State of Pennsylvania, and signed by the President, be sent to each member of the Pennsylvania delegation in Congress, and to the Chairman of the Committees on the District of Columbia, of the Senate of the United States and of the House of Representatives.

The preambles and resolutions were unanimously adopted. Copies were at once forwarded as directed and several replies were received from members of Congress favorable to the action asked.

DR. E. B. BORLAND, of Pittsburg, read a paper on the "Prevention of Tuberculosis." His conclusions were the three essential factors of infection, debility, abrasions and bacilli. There are two principal routes of infection, two sources of infection. He then spoke of the transmission of infection, of the vitality of the tubercle bacilli, of measures to prevent infection in milk and in sputum, ways and means to stop expectorating on floors and sidewalks, of destroying sputum in cuspidores, of ventilation, legislation, education, house disinfection, isolation and care of patients in the ulcerative stage.

DR. J. C. LANGE, of Pittsburg, read a paper on "The Antiseptic Factor of the Treatment of Typhoid Fever." He proposed external antiseptics of the whole body, of the orifices of the body and of the intestinal canal.

DR. H. S. MCCONNELL, of Brighton, read a paper on "Elimination, Starvation and Antiseptics in Typhoid." The accepted pathology shows that this disease is due to a microorganism. He denied that typhoid fever is a self-limited disease. Its duration and gravity depend upon our ability to prevent and destroy the bacilli and restrict and eliminate the toxin. Eberth's bacillus being the cause, the point of attack the alimentary canal, three indications are to be met: 1, to prevent the introduction of any bacilli; 2, to destroy and expel all bacilli in the digestive tract; 3, to make and keep the intestinal canal aseptic. The first is done by permitting only sterilized substances; the second by active purgation; the third by intestinal antiseptics, prohibiting all and every kind of food for three days. After this, when there is unmistakable hunger, give food well diluted, at long intervals and in small quantities; half a teacupful of hot water every hour, and an enema of salt and cold water morning and evening. Keep temperature below 102, cold sponging, over this guaiacol externally. He had thirty-four cases, with one death; duration eighteen and three-tenths days. There were four relapses, one hemorrhage. One went seventeen days without food, another fifteen days, and thirty-two from seven to twelve days. He claimed this to be the rational treatment. It shortens the disease, temperature soon falling to normal line. There is very slight delirium, no illusions, less liability to hemorrhage or perforation. The patient is comfortable and in convalescence we have a stomach that is capable of digesting food.

DR. T. P. SIMPSON, of Beaver, read a paper on "The Use of Alcoholic Stimulants in Typhoid." The gist of this paper was a protest against the apparently increasing practice of giving alcohol freely and carelessly, with an attempt to show why this may be harmful and defeat the object sought to be reached, ending with a description of the cases which require alcohol and an estimate of the amount usually needed. These were discussed quite freely by a number of the members.

DR. J. M. BATTEN, of Pittsburg, read a paper on "The Therapy of Veratrum Viride." He gave a brief history of the drug. He dwelt upon its usefulness in the treatment of diseases of an inflammatory type by keeping the pulse at or near the normal, and especially of inflammatory diseases of the chest. He next gave a brief history of two cases of acute pneumonia in which the drug was used satisfactorily.

Some discussion next ensued upon the proposition to issue the transactions in a quarterly journal, and the subject was laid upon the table. A report of the Committee on the Rush Monument Fund showed very little progress in the matter.

SECOND DAY—MAY 20.

The Secretary read a telegram from the Secretary of the State Medical Society of Illinois:

"The Illinois State Medical Society sends cordial greeting.

"JOHN B. HAMILTON, Secretary."

The following reply was directed to be sent:

"Greetings cordially reciprocated. Have passed emphatic resolutions against the proposed vivisection legislation at Washington; hope you will do the same.

"W. B. ATKINSON, Secretary."

The Nominating Committee was announced and directed to meet at once.

DR. J. J. BUCHANAN, of Pittsburg, delivered the

ADDRESS IN SURGERY.

He asked the consideration of a few of the common things in surgery, most important because so common. Perhaps the most important is appendicitis. The divergence of opinion as to treatment increases the responsibility of the attendant. The expectant treatment is fraught with anxiety. Drugs have no place here. Opium only covers up the symptoms. Purgatives may do worse. With rest, diet, nursing and abstinence from drugging, many do recover. Who is to assure safety? Perforation may convert the case into a hopeless one. It seems the course of greatest safety is to remove the appendix early. Consent early is difficult to obtain, especially if a mild case. Still if the period of primary operation has passed, and an exudate has formed with an abscess of considerable size at its center, the operation becomes a matter for grave consideration. The gravity now depends on the position of the adhesions. If the appendix can be reached without opening the peritoneal cavity it is safe. If the cavity has to be reached and drained across this serous sac, the operation is hazardous, and often fatal. Many have no hesitation in dealing with such abscesses across the peritoneal cavity, protecting it with gauze packing. However skillful, the fact remains such are often followed by septic peritonitis and death. With the present technique, it is more prudent to attack these abscesses at a point where adhesions have probably occurred. Whether the appendix should always be sought and removed after evacuation of the abscess has caused much discussion; but the conclusion of most is that if easily accessible, it should be removed, but if imbedded in the abscess wall and the removal would imperil the integrity of the latter and risk opening of the healthy peritoneum, it must be left alone. The most positive advance of the year seems to be in the tendency to operate on cases of recurrent and chronic appendicitis between attacks. He insisted that two periods are when the removal is safe, in the very beginning and in the interval between attacks, and all cases seen at either period should at once be operated on, if the diagnosis is clear and consent is obtained. In fractures, the essential factor in repair is callus. The indication is to secure a moderate amount of this; the most favorable condition for its formation is a full blood supply and keeping the parts in approximation and quietude without absolute immobility. A revival is seen in the plan of open incision and fixation in simple fracture. Since antiseptics has been brought in, attempts have been made to bring this into general use, but the results without this have been so good as to prevent its general use. But when reduction can not be satisfactorily made and the site of fracture is accessible such are treated with great success, the apposition can be perfect and fixation by pegs or suture secured. The result justifies the risk and deformity may be prevented. Two errors are to be avoided. Not to apply this on such as can be treated without, and not to remove detached fragments of bone which are valuable for consolidation. In these cases the process of repair is a little more protracted; still it is certain that it is destined to have a wider application and with proper limitations will be very valuable. The most frequent changes advocated in fractures is that allowing greater freedom to the part, the ambulatory treatment and that by massage and passive movements. The first consists in approximating the fragments, applying a fixation dressing by extension which can be kept up by its application against points of vantage as the tuberosity of the ischium for fractures above the knee and the head of the tibia for fractures below the knee; and elevation of the sole on the sound side and a prolongation of the splint to a corresponding distance below the sole on the injured side. Permit the patient to bear the weight of the body alternately on the two sides, the weight being transmitted on the injured side, from the tuberosity of the ischium or the head of the tibia, as the case may be, through the splint to the ground. Thus he escapes confinement to bed and has the benefit of out door exercises. It is said that muscular atrophy is prevented and the gentle stimulus of motion hastens union. By massage at or near the seat of fracture with passive movements of the

near joints is a method which entails great labor, but has much in its favor. The ideal treatment of simple fractures after reduction should meet the following indications. Retain the fragments as near the normal as may be. Splints or other dressings should be easily removable without disturbance of the fracture. No constriction to impede the circulation. Dressings to be removed at short intervals to permit examination, massage of the callus and neighboring muscles, gentle stimulation of the growth of callus by the slight disturbance incidental to removal of and reapplication of dressings and passive movements of adjacent joints, when these can be done without disturbing the relation of the fragments. The most important accessory is the removable splint which fits the part so accurately that the reapplication is never a matter of experiment and is so light as to be no burden. He preferred the plaster of paris splint, as easily and quickly applied, fits accurately, causes no discomfort, can be removed and reapplied as needed. The cost is trifling and it is portable. In its application, an outline of the shape desired is cut from a double layer of lintine, a firmly compressed cotton sheeting. One layer is placed on a table and two gypsum rollers are soaked in plain cold water till the air bubbles cease to rise. One of the plaster rollers is then spread on the layer of lintine as it lies on the table. The plaster roller is passed back and forth, end to end of the lintine till the figure is entirely covered from four to six thicknesses. This is laid as smoothly as may be and can be made thicker at some parts if desired. When the desired thickness is attained the other piece of lintine is applied to the upper surface, to which it will adhere. The edges are then trimmed with scissors, where the plaster overlaps and the splint is ready for application. It is as flexible as a wet dishrag. The limb is elevated and the splint applied to the surface and held by an assistant. The application of a roller adapts this moist and clinging splint exactly to every inequality. The limb can now be placed on a pillow and steadied, while a splint of the same kind is prepared for the other aspect of the limb if necessary. By the time this is ready, the first will be found hard enough to support the part. The second is applied to the other aspect over the muslin roller and the dressing is complete, and in ten minutes will be hard. When desired to remove and reapply, each should be applied in its turn and with its own roller. Thus no part of the limb can be pinched between the edges as often happens when both splints are applied directly to the skin by a single roller. No paddings should be placed next the skin, unless as a dressing as in compound fracture. All dressing must be light and be duplicated when the splint is removed. Should the splint cause discomfort by pressure this part should be cut off and pressure will be at once removed. In conclusion he called attention to the advantages of the infusion of large quantities of normal salt solution into the veins after hemorrhage from accident or operation. One or two pints are often used, even many quarts. He had reported a case with profound loss of blood from a limb crushed so as to need amputation, into whose veins during the six hours before operation, he infused six quarts of saline solution with the gratifying results of reaction and recovery. Later he had used even larger quantities with marked benefit. He was convinced that this procedure is not appreciated and the failure of the salt solution is from the want of a sufficient quantity and the abandonment of the treatment too soon.

Dr. J. W. MOORE, Easton, read the

ADDRESS IN HYGIENE.

The writer believes that there is real danger to the cause of sanitary reform from too hasty acceptance of theories which result in proposing, adopting and enforcing regulations which are a hardship to the people without accomplishing good. Every regulation founded upon theories which have failed to stand the test of scientific examination react in the minds of the voters to the detriment of the cause. Having these views he showed the weak places in the modern theory of the origin and dissemination of contagious diseases. He claimed that evidence from clinical, bacteriologic and epidemiologic sources must agree and that in particular diseases they did not and therefore the parasitic origin is not proved. Opinions can not establish contagion nor analogy nor imperfect induction from insufficient data. Science is often retarded by the expression of opinions by learned men. Newton himself is responsible for the backwardness of the science of optics. We must avoid the confusion of coincidences with similarities. The old proofs of contagion are not obsolete; truth never is. But in the case of tuberculosis, for example, they will not apply because the disease is too old, the distribution too wide and the cases too chronic. The modern theory of parasitic origin of disease is fascinating and has many points which appeal to our minds by their truthfulness. The researches of Koch, Pasteur and others

have opened a boundless field for investigation. Let us honor them always. In this department of science as in others the disciples with less knowledge claim more than their masters. Koch for example insisted upon four postulates; many of his followers accept contagion on even one; some on none proved. These postulates have become rather ancient history, but Koch was right; they are not axioms which are self evident but postulates, the truth of which may be denied. In the meantime other questions have been opened up which make the investigation still more difficult. The crucial test of the theory is the reproduction of the exact disease in man; this had not been effected. The results of a laboratory experiment can not be predicated of an experiment performed by nature in her own way; so many new conditions are introduced that to conclude from the first that the second will show the same outcome is absurd. The possibility and the probability of infection must be distinguished when the question of actual contagion is taken up for discussion. The conditions are so different that the experiment is practically not the same. The same disease is not equally contagious under the same apparent circumstances; the same disease is not equally communicable to different persons nor to the same person at different ages. Hence all contagious diseases are not to be subjected to the same regulations.

Dr. J. M. BALDY, of Philadelphia read a paper on

PELVIC PERITONITIS

from the standpoint of the general practitioner. Acute pelvic peritonitis has received little consideration of late years from this standpoint, the impetus generally being surgical. A surgeon naturally prefers surgery, but the physician is apt to adopt the methods in which he has the most confidence. Both may be right within limits. An attack may be due to a chronic disease of the Fallopian tubes which may have existed for years. Therapeutics may cure the existing peritonitis but fail to cure the woman. He desired to impress two aspects, the diagnosis and the more important non-surgical methods of treating this trouble. The diagnosis is important, as it aids materially in the conduct of the case for or against operation. It is a fact that such cases are often treated rationally without a knowledge of the exact cause. But it is not right to act thus in the dark. Still the cause can not always be detected even by the most skilled. The medical treatment is to a great extent routine; rest, depletion and relief of pain. Opium fulfills two indications—rest and relief of pain, but defeats the third, depletion. Rest in bed must be followed by functional rest. If in no other way by large soft vaginal tampons worn between treatments, frequently replaced and not so as to press upon the posterior parts of the vagina too firmly. Wool is best. Depletion is obtained in two ways. Direct scarification or leeching of the cervix gives remarkable relief. The great remedy is hydragogue cathartics, the salines. A teaspoonful of magnesium sulphate each hour till the bowels operate. Secure half a dozen or more movements in a few hours, the last being purely serous. Often the attack will subside with the purgation: the abdominal distension subsides, pain and tenderness are relieved, pulse is normal and convalescence ensues. Hence it is not believed to be peritonitis. Abdominal section frequently shows an abdominal and pelvic peritoneum free from trace of inflammation. Such are the cases which are relieved by a purge. In true inflammatory attacks, the purge is only a step in the treatment. If magnesia is rejected by the stomach, calomel in grain doses half a dozen times, followed if possible by one or two doses of saline, and finally a large enema of hot soapsuds is an excellent substitute. The peristaltic action thus caused often increases the pain. If unbearable, opiates in form of hypodermatics of morphia (one-sixth or one-fourth) need not be feared if needed. Depletion thus obtained should be followed by the application of the vaginal douche twice daily. Its first effect is to cause congestion, and unless pushed to the extent of procuring the secondary effect of the hot water (the shrinking and blanching of the tissues) it will do harm. Counter irritation, poultices, etc., are of doubtful value. They may serve the purpose of allaying the mental condition. The attack will be of more or less duration as the underlying disease. Attacks which keep the patient in bed a month or six weeks are to be suspected of suppuration. Diet should be regulated and the excretions kept in good condition. Antipyretics are not needed. When up, she must avoid all undue exercise or sexual indulgence till pain has entirely gone. Proper regulation of clothing, etc., need not be emphasized.

Full discussion by a number ensued on this practical paper. Dr. JAS. FULTON, of Chester, read a paper on "Alcoholic Stimulation in the Treatment of Disease." He endeavored to show why such remedies are so popular with the community at large; why so generally used by physicians in typhoid fever, in consumption, in delirium tremens, shock, etc.

DR. G. HUDSON MAKUEN, Philadelphia, read a paper on

THE DIAGNOSIS AND TREATMENT OF SPEECH DEFECTS.

He exhibited a little boy who read quite well and clearly as the result of his efforts. After discussing the importance of speech as a factor in mental and physical development, the possibilities of its improvement and the complexity of its mechanism, he said that with our present limited knowledge, any classification of the defects of speech is difficult to make, but they may be divided with reference to their causes, into two general classes, namely, those of cerebral and those of peripheral origin. He then cited from his note book three cases to illustrate how difficult it is oftentimes to determine the exact cause. One case, a boy 19 years of age, with arrested development of speech, and the other two stammerers. It was supposed that the first case was of cerebral origin, but both the first and second cases were cured completely by simple operations, the first by the division of the anterior fibers of the genio-hyo-glossus muscle and the second by the removal of an adenoid growth. This patient was exhibited to the society. The third case is still under treatment directed toward the reduction in the size of the epiglottis. He said he would operate for defects of speech only when there are structural peculiarities or pathologic conditions interfering with the normal action of the organs. He thought even slight obstructions sometimes cause trouble and should be removed, especially when they are found in children. They interfere either mechanically or reflexly through the nervous system, but more often in both ways. After these irregularities have been corrected and obstructions removed the faulty habits of speech must be broken up by appropriate exercises. Only those having made a special study of speech can do this successfully. He said no definite rule can be laid down as to the special kind of training. The exercises must fit the case. They must develop undeveloped muscles. He closed by saying that many cases have been supposed to be of cerebral origin and incurable which were in reality due to some slight abnormality in the peripheral organs which if detected would easily be remedied, and he urged the necessity of greater care on the part of the profession in the study of these cases.

DR. J. W. ROOP, of Harrisburg, read a paper,

GELSEMIUM AS A REMEDIAL AGENT.

The root is used, though the flowers and leaves contain the medical properties in large quantities. The effects depend on the presence of an alkaloid soluble in ether and chloroform, less in alcohol or water. It is more particularly valuable in controlling nervous irritability in periodic fevers of a malarial type. Lately it has attracted attention for neuralgic attacks. The earliest symptoms in large doses are dim vision, drooping eyelids, inability to open the eyes, etc. Antidotes are nitrite of amyl by inhalation or hypodermically. This acts instantaneously as a nerve and arterial stimulant. Also, carbonate of ammonia, brandy, morphia, electricity, till the poison is eliminated. In twenty-six years' experience he had used this drug thousands of times without toxic effects, in tincture or fluid extract, and was convinced that it is a most valuable remedy, beginning to act in half an hour and ceasing in one or two hours. He preferred the tincture as safest. Dose, five drops to adults; to children, in proportion till the physiologic effect is obtained, that is, dim vision, etc. Then omit till these pass off and resume. In facial neuralgia and nervous headaches it has no rival. It may be combined with muriate of ammonia, or with quinia; it corrects ringing of the ears and the headache often produced by quinin. It promotes the action of this drug and in diminished doses. In chronic malaria, gelsemium with liquor potassae arsenitis is valuable, preventing relapses. The cough of bronchitis is relieved by it. Acute muscular rheumatism is also amenable to it, the patient being put under blankets and three to five drops given every hour till free sweating results. With nuxvomica it has a remarkable influence on the spinal nerves. Many nervous affections are cured by it in this combination. Added to the bromids, it often cures neuralgias of nervous women and relieves the pain and tormina of the bladder, and in diseases of the rectum. With belladonna or morphia it increases their anodyne powers. In infantile inflammations in quarter or half drop doses it is of great value. In rigid os uteri, etc., in puerperal convulsions and nausea and vomiting of pregnancy, he has found it of value. Where opium is contraindicated, it comes in with good results. As a guide for its use, he laid down the rule that where we find a flushed face, bright eyes and contracted pupils it is the remedy, either alone or combined as indicated.

DR. E. E. MONTGOMERY, of Philadelphia, read a paper on

THE TREATMENT OF PELVIC INFLAMMATORY CONDITIONS THROUGH VAGINAL INCISIONS.

He advocated the practice of vaginal incisions for pus collections in the broad ligament, in the tubes, when large purulent or serous collections in the pelvis, for exploration and for the evacuation of hematocele. He preferred abdominal incision for the removal of one ovary or tube and for fixation. Cases of retrodisplacement with adhesions may be treated as suggested by Pryor, by opening the posterior fornix of the vagina, breaking up adhesions, replacing the uterus and maintaining it in position by gauze packing. In cases where the functions of both ovaries and tubes are destroyed, so as to render their removal necessary, the vaginal route affords, in the majority of cases, the most favorable way for the removal of the diseased structures, and the uterus should be removed with the appendages.

At the afternoon session the Committee on Nominations reported the following: President, E. E. Montgomery, Philadelphia; vice-presidents, C. S. Shaw, of Pittsburg, F. P. Ball, of Lock Haven, T. M. Livingston, of Columbia, and A. C. Wenz, of Hanover; secretary, William B. Atkinson, Philadelphia; assistant, Adolph Koenig, Pittsburg; treasurer, Geo. B. Dunmire, Philadelphia; and censors and delegates to sister societies and the AMERICAN MEDICAL ASSOCIATION and the Pan American Congress.

Pittsburg was selected as the place of meeting for 1897, with Dr. T. D. Davis, of Pittsburg, as Chairman of the Committee of Arrangements.

DR. ISRAEL CLEAVER, Reading, read the "Address in Obstetrics." He alluded to the work under this head for the period since 1873.

DR. F. S. PEARCE, of Philadelphia, read a paper on

A CLINICAL REPORT ON THE USE OF TESTICULAR FLUID INJECTIONS.

Males, 30; females, 10. The diseases were locomotor ataxia and the sclerotic cord diseases, paralysis agitans, neurasthenias, especially of the sexual type. Injections were given under strict antiseptic precautions in the buttocks or thighs or arms. Passive massage of the parts was practiced to encourage diffusion, and thereby prevent irritation. In the 500 injections given by Dr. J. K. Mitchell and the writer, there had been but two abscesses produced. Average amount of injection that seemed to act most advantageously was between twenty and thirty minims, diluted with distilled water. Every other day seemed most desirable time for injections in order to prevent irritation, which frequently occurs. If pushed to the point of endurance, the B. S. Fluid produces nausea, vomiting or diarrhea.

In the nineteen cases of locomotor ataxia treated, sixteen were in males, of which eleven seemed to be stimulated to at least temporary improvement by the remedy. In five cases no result was obtained. In one, injections of water acted the same as B. S. (psychic). A large proportion of these ataxias were in the advanced stage of the disease. Sexual power was much reduced or, indeed, impotence existed. Of the eleven male ataxic cases improved, the effect was of a general stimulation of the nerve tonus; described by the patients as a sense of "well-being." There was an ease of breathing and increase of pulse force, as though the respiratory and cardiac centers were buoyed up to more active work. In some ataxics increasing muscular strength and co-ordination was attained; the patients being able to endure more exertion. This was especially noted in number 22, who persisted that he could feel stimulation creep over him as early as twenty minutes after the injection. He finally had nausea and diarrhea, due to the effects of too large dosage.

Pain was somewhat lessened in three cases. Along with the general stimulation and bettered coördination in the eleven males quoted, there was in addition, in four of them, as seen above, very marked increase of sexual power and a general sense of comfort. The above series of ataxic cases present positive results. The remaining cases did not carry out the treatment, or else it proved inefficacious, in both of which instances they are classed together as failures. From the above cases it can not be concluded that the effect of testicular extract is to produce sexual increase mainly, but rather that the sexual increase falls in line with the general stimulation, but not always so. What is most clear in any of the cases in which we have used the drug, is that a general stimulation is the most frequent method of its action for good. To the above cases Dr. S. Weir Mitchell can add two occurring in old men in which B. S. injections caused this general stimulation and great increase of sexual power, the latter so much so as to be annoying in one case. The Brown-Séguard treatment has proven of stimulat-

ing and rejuvenating power in disease of chronic nature where nerve energy at a low ebb, whether in organic or so-called functional neuroses; and these aside from psychic influence. The effect may be to increase oxidation or to supply something the body needs, as in other organo-therapy, and thus to supply a temporary tonic to the system which acts by general stimulation; it at times relieves pain and crises in organic cord disease; it may greatly stimulate the sexual function. There can be no claim made for this agent to act as a cure per se in any malady, certainly not in any sclerosis. It may prove one of the aids toward recovery from the vicious circle of disease. There seems to be no criterion to judge the cases in which good or failure may be expected. Sometimes an unexpected happy impetus to waning vital powers may be rekindled by the drug, which does good for the time being, and paves the way for other therapeutics to take hold of the system. It may too open the blood paths more widely about a sclerosed area and thus add to nutrition of the part transiently. It is not intended to laud the remedy, but to present the clinical evidence of its limited usefulness in disease.

DR. JAMES M. ANDERS, of Philadelphia, read a paper on

SOME THERAPEUTIC USES OF GUAIACOL.

That guaiacol is a valuable medicinal agent is allowed by all who have employed it in suitable cases. The complaints in which it is serviceable are divisible into three groups, which are considered separately.

Group 1. Febrile Affections. These are acute and chronic. Of the acute febrile diseases in which it has been used, typhoid fever, the pneumonias, lobar and lobular, stand foremost. It is an antipyretic when applied to the skin in the proper amount, and according to the experience of some of the physicians who have thus used it most extensively, it is practically free from unfavorable effects. Dr. H. G. McCormick has applied guaiacol more than eight hundred times in typhoid fever with uniformly good results. He has occasionally observed chills, but these were noted when the temperature as the result of a topical application of guaiacol, dropped below 100 F., and they were not followed by increased fever nor increased weakness. The occurrence of rigors is a certain indication that the dose has been too large and hence should be lessened immediately. On the other hand, while he has used guaiacol in but two cases of typhoid fever, in one of these its use was attended by rigors both on the thirteenth and sixteenth days of the affection, followed by a rapid rise of temperature to a higher level than the previous maximum temperature. Rosenthal, of Philadelphia, observed a similar effect in a case of typhoid fever. Thayer has also reported marked chills from its use. Still other observers have noted a decided weakening effect when guaiacol was employed as an antithermic agent. But though guaiacol does not possess the obvious and numerous advantages for the patient that the Brandt method does, it may very properly be employed in cases in which the cold baths can not be instituted on account of the existence of an insurmountable prejudice, or of contraindications to the latter, such as intestinal hemorrhage, acute nephritis, otitis media, etc. Its internal administration in the form of the carbonate of guaiacol in typhoid fever is to be highly recommended since it reaches the intestinal canal before it is disassociated or absorbed. Under these circumstances there is opportunity for the remedy to make a direct attack upon the typhoid bacillus. I have had no personal experience with guaiacol in the treatment of typhoid fever, but have used it in acute and chronic forms of intestinal catarrh, accompanied by fermentative processes with truly excellent results. In a paper previously published may be found the report of a case of broncho-pneumonia in which this antipyretic was employed (in half dram doses), the patient making a good recovery. The applications of the remedy were not followed by so marked a reduction of temperature as in typhoid. More recently, I have used guaiacol in two additional cases of broncho-pneumonia with like results. It would appear from my own observations that fever dependent upon local inflammations is to a less extent reduced by guaiacol than when due to general causes. Pulmonary tuberculosis is the one chronic febrile disease in which guaiacol has been frequently employed. J. S. Cohen has noted a striking reduction of temperature following its external use in this disease. I have employed it in a few instances of chronic phthisis quite recently, and while it has reduced the temperature decidedly, the profuse sweatings and occasional debilitating effects induced by the remedy, have led me to abandon its employment in this affection.

Group 2. The second division of cases are the non-febrile. These embrace chiefly myalgic and neuralgic pains. The local physiologic action of guaiacol is that of a decided sedative. Thus, when administered internally it allays the irritability of

the nerves terminating in the gastric mucosa. In the paper referred to there are reported cases of gastralgia successfully treated by guaiacol, given in doses of two or three minims, combined with glycerin. Later observations have confirmed the favorable opinion previously expressed as to the value of this agent in gastric hyperesthesia or irritation of the sensory nerves of the stomach, when cautiously used. Ferrard first employed this drug in sciatic and other forms of neuralgia (painting it over the course of the nerve, mixed with an equal part of glycerin). Eight cases of neuralgia in which guaiacol was the chief reliance I have reported previously. In three of these, the drug was exhibited hypodermically, the dose being one or two minims combined with ten minims of spirits of chloroform. I can now add the results obtained in four additional cases of neuralgia treated in this manner. To be brief, among them, two affected the supraorbital branch of the fifth pair, one the intercostal nerves and one the left sciatic nerve. In one of the cases of supraorbital neuralgia there was a distinct history of antecedent malaria, hence quinin (20 gr. daily) were exhibited *per os*. Additionally, two minims of guaiacol and ten minims of chloroform were administered subcutaneously at the point at which the nerve emerges from the deeper structures. This was repeated at the end of twenty-four hours, after which the pain ceased permanently. In the other case of this form of neuralgia no special causal factors, except, perhaps, exposure to cold and wet, could be ascertained. Here it was necessary to inject the guaiacol twice daily for two days before permanent relief was obtained. One of the cases of intercostal neuralgia in which this agent was employed arose in an anemic and neurasthenic female. Beside the means, internal and sanitary, usually resorted to in such cases guaiacol was applied externally during the first week, with the result of affording only temporary relief. Subsequently the guaiacol was exhibited hypodermically. After the fourth puncture the pain yielded and has not since returned. In the case of sciatic neuralgia injections of guaiacol failed to cure, but greatly relieved the pain when administered at intervals of eight or ten hours. Thus eleven out of twelve cases of neuralgia were successfully treated by the use of guaiacol. In one-half or six of the instances the drug was used hypodermically, with five cures. In some of the latter the pain showed great obstinacy, and was not relieved by the external use of the drug, but yielded when it was injected subcutaneously. Muscle pains due to cold, old sprains or rheumatism are also promptly relieved by the local use of guaiacol.

Group 3. Inflammatory Processes. Guaiacol has been used by myself and others in acute forms of inflammation, especially the rheumatic. As I said elsewhere it serves admirably to relieve pain of rheumatic origin, "but it does not appear to cause any reduction of rheumatic inflammatory processes." In no form of acute inflammation have I been able to observe any antiphlogistic effects from the employment of this agent. A few inferences which are based upon personal experience, may here be stated and emphasized with a view to facilitating a discussion of the subject of the therapy of guaiacol: 1. Guaiacol effectually reduces the temperature in febrile affections, but it may produce objectionable effects such as profuse sweatings and rigors, followed by high temperature. 2. In afebrile diseases it is free from unpleasant effects. 3. It is an effectual local anodyne, both when administered internally and to the skin surface over the seat of pain, but it is especially potent to relieve neuralgic and myalgic pains when administered hypodermically. 4. It is "powerless to control inflammatory processes, particularly when they are acute in character."

(To be continued.)

Illinois State Medical Society.

Abstract of the Proceedings of the Forty-Sixth Annual Meeting, held at Ottawa, May 19, 20 and 21, 1896.

(Concluded from page 1130.)

DR. NORVAL H. PIERCE, Chicago, made some remarks on the "Modern Pathology and Treatment of Acute Middle Ear Inflammations."

METATARSALGIA, WITH A REPORT OF THREE CASES OF WHAT IS TERMED MORTON'S PAINFUL AFFECTION OF THE FEET

was read by DR. A. E. HALSTEAD, Chicago. After dealing with this subject in an exhaustive manner, the author drew the following conclusions:

1. That what is known as metatarsalgia is not in the beginning a distinct pathologic entity, but rather an early symptom of static flat foot. In cases of long standing, irritation of the plantar nerves by pressure of the transverse metatarsal arch

may cause an inflammation of the nerve, or even in some cases the development of a neuro-fibroma.

2. That most of these cases can be permanently cured by following the treatment usually employed in beginning flat foot—*e.g.*, systematic massage, gymnastics, and the use of properly fitted shoes, and in some cases the application of a metallic brace to the sole of the foot.

3. In cases of long standing, where there is well-marked pathologic change in one or more of the branches of the plantar nerves, resection of the nerve should be performed. The more radical operations, such as resection of the metatarsophalangeal joint or amputation of the toe, are not indicated.

Dr. E. MAMMER, Bloomington, read a paper entitled

CHOLELITHIASIS; A PLEA FOR OPERATIVE TREATMENT.

All cases which are not promptly relieved by the passage of small stones, or by therapeutic measures effectively and judiciously employed, at once furnish true indications for resort to cholecystenterostomy. The operation can be safely done and will be successful when calculi are in the gall bladder only, when they are in the gall bladder and in the cystic duct, and when they are in the ductus communis choledochus, and can be removed, or when, even if left there, the bile will find a free passage by the new channel; in febrile cases, where the stone or stones are impacted behind the duodenum, and where the new channel will allow passage for both bile and pancreatic fluid into the bowel, provided no purulent inflammation has preceded. So long as such cases have not gone too far, cholecystoduodenostomy, preferably by means of a No. 2 Murphy button, will furnish a safe and easy remedy.

Indications for operation in such cases as the above may be obtained by carefully weighing all symptoms and a thorough study of them in all their relations. The author reported two cases upon which he had operated successfully. He made an eloquent plea for early operation in gallstone cases, and closed by saying that to wait until all internal remedies failed was not rational, for no remedies existed against large calculi. By the timely advice of the physician and the surgeon's technical skill, patients with hepatic calculi should be early and readily relieved, and thereby the percentage of recoveries would be materially increased.

VAGINAL SECTION FOR THE CURE OF RETROVERSION OF THE UTERUS

was the title of a paper read by Dr. HENRY T. BYFORD, Chicago, in which the author described the technic of the method which he had employed, as follows: The vulva and vagina are thoroughly scrubbed with soft soap, then with strong alcohol and with a 1 to 2,000 solution of bichlorid of mercury. The uterus is dilated and curetted and disinfected with mild or strong solutions according to the requirements of the case, or the notions of the operator. This preparation is necessary to prevent the infection of the connective tissue and buried ligatures.

A transverse incision, a trifle over an inch long, is made in the vaginal wall just in front of the cervix, and the bladder separated from the uterus by the finger as far up as the peritoneal reflection. Then a longitudinal vaginal incision about two inches long is made in the median line from the neck of the bladder to the middle of the transverse incision. The bladder is separated from the vagina for a short distance on either side of the incision to give room for manipulation. The peritoneum is then torn across between the uterus and bladder, an intraperitoneal pelvic examination is made, adhesions are separated, and such parts are treated or removed as may require it. The bladder peritoneum is then seized by forceps and drawn down by successive grips until that which belongs behind the pubes can be seen. Two chromicized catgut threads are introduced about one inch apart through this portion of the peritoneum and subperitoneal tissue as high as possible. Then the anterior surface of the uterus is grasped with tenaculum forceps, and the fundus pulled into the vaginal wound and attached to the bladder by means of the above mentioned catgut threads. The finger is now hooked over the left round ligament, which lies beside the vaginal wound, a loop of the ligament drawn into sight, grasped by forceps and pulled down until the inguinal end is taut. A catgut suture is put through it as far from the uterine end as possible and is made to attach to the uterus just above the normal uterine insertion, which is easily exposed to view by the vaginal retractors. The same is done to the right ligament. The entire vaginal wound is closed with transverse sutures that reunite the bladder to the vagina, and also draw the ends of the transverse incision together, leaving one row of sutures in the median line. This lengthens somewhat the anterior vaginal wall and draws the connective tissue together in front of the cervix. A few inches of a narrow strip of gauze

is placed in the connective tissue in front of the cervix, to be removed in twenty-four hours by pulling on the end which projects between the sutures into the vagina.

Dr. Byford has operated upon ten cases in this manner, beside one case in which he merely sutured the fundus over the bladder, and in each one the uterus has remained in a normal position without the aid of a pessary at any time. The comfort is greater and the complaint much less than after Alexander's operation, and the patient is not conscious of a wound or sore place. In addition to these advantages the gynecologist obtains, while operating, a definite knowledge of the conditions of the pelvic organs and the possibility of correcting them.

The uterus has no abnormal attachments except the two points of peritoneal adhesion to the bladder, and there can be nothing to fear from subsequent pregnancy.

Dr. A. H. FERGUSON, Chicago, read a paper entitled

IODOFORM INJECTION TREATMENT OF HIP-JOINT DISEASE.

The intra-articular medication of tubercular joints, he said, was of recent date and was not yet very widely employed. It was with the hope of stimulating the profession to use it more and more that he presented his views on and experience with this treatment. The hip-joint had been selected on account of the frequency with which it is diseased, and because, in the speaker's hands, it had been more amenable to the iodoform emulsion injection than any other joint.

The objections to the hitherto recognized methods of the treatment of hip-joint disease were: 1, the high rate of mortality; 2, the long time that the patient was under treatment; 3, the great deformity that so commonly ensues; 4, the complications that are liable to set in and carry off the patient. The author then outlined the manner of using intra-articular injections of iodoform emulsion.

As to the time of treatment, the longest period that he deemed it necessary to pursue the injection method before a cure was effected, was nine months, and it was a case well advanced in the second stage. He had treated upward of twenty-five cases with the most satisfactory results, and which so far appear to have been cured with the exception of two cases, one who refused to receive the subsequent injections, and the other had marked tuberculosis of the apices of both lungs, but he gained over twenty-five pounds during the five months he was under treatment.

ANNUAL DINNER.

The second annual dinner of the Society was held in Armory C. Dr. John B. Hamilton, Chicago, acted as toastmaster. The toasts were responded to as follows:

"The Clergy," by Father H. A. O'Kelly, Streator.

"The Bar," Hon. Duncan McDougall, Ottawa.

"The State Medical Society," President Dr. David W. Graham, Chicago.

"The Ex-Presidents," Dr. John H. Hollister, Chicago.

"The AMERICAN MEDICAL ASSOCIATION," Dr. E. P. Cook, Mendota.

"The Pharmacists," Mr. Rogers, Chicago.

"Our Guests," Dr. James T. Whittaker, Cincinnati, Ohio.

"The Young Physician," Dr. E. J. Brown, Decatur.

"Our Medical Journals," Dr. O. B. Will, Peoria.

"The Ladies," Dr. Fenton B. Turk, Chicago.

Dr. Norval H. Pierce, Chicago, rendered two musical selections which greatly pleased the audience.

THIRD DAY—MORNING SESSION.

Section One—Third Session.

Dr. F. C. ROBINSON, of Wyandot, read a paper on the "Treatment of Tuberculosis by Aseptolin." The author reported one case treated by this remedy and declares it an absolute failure, and says it is unworthy the confidence of the profession.

Dr. E. W. ZOOK, Peoria, followed with a paper on WHAT MEASURES BEST RESTRICT THE SPREAD OF TUBERCULOSIS.

The restriction of the spread of tuberculosis, while not a new subject, was one that had not been given the attention it deserves. The author believes that the time is not far distant when a specific cure for tuberculosis will be discovered, but until that time comes, we will have to rely upon preventive measures, and if these can be uniformly enforced, he thinks we will without doubt be able to check the spread of this disease, but in order to do it we will have to put forth our best efforts.

Dr. H. W. GENTLES, Chicago, read a paper on "The Pathology and Treatment of Chronic Alcoholism."

Dr. ALEX. C. WIENER, Chicago, read a paper entitled

PERMANENT AMBULATORY EXTENSION IN SURGERY.

He said that in fractures of the shaft of the tibia or femur absolute immobilization of the bones in the normal position either by compression bandages or weight extension is indis-

pensable, but is it absolutely necessary to have the patient rest in bed all the long weeks until consolidation is perfect? The speaker replied in the negative. The surgeon gives his patient a dressing tightly fitting to the outlines of the extremities so as to keep the fractured bone in a correct position and to regulate the impaired circulation so that the injured can put his legs on the floor without pain. In order to allow the patient free mobility the patient is supplied with an apparatus which Dr. Wiener described and which seemed to be very practical and useful in the treatment of the cases under consideration.

Section One—Third Session.

DR. J. M. G. CARTER, Waukegan, in a paper entitled

FUNCTIONAL INDIGESTION, ITS CAUSES AND TREATMENT,

stated that the term indigestion referred to a condition, not a disease. This disturbance then was always functional. The following indications may be regarded as pointing out the course of correct treatment in the class of cases considered in the paper, to be varied to meet the necessities of individual patients; 1, remove the cause; 2, check or prevent the growth of bacteria; 3, assist digestion, and 4, repair damages done. These indications were then dwelt upon at length.

In conclusion, he said that the causes of functional indigestion were some indiscretion in diet; some irregularity in the time or manner of taking food or drink; the presence of certain species of bacteria; some neurosis or reflex disturbance; some sudden mental or emotional excitement.

DR. FENTON B. TURCK, Chicago, made some remarks upon the pathology of gastritis and demonstrated his method of treating this affection on a patient. He went over substantially the same ground as that covered in his previous and numerous contributions to medical literature on this subject, and with which most readers of the JOURNAL are more or less familiar.

DR. E. S. PETTYJOHN, Alma, Mich., read a paper entitled
THE DIFFERENTIAL DIAGNOSIS OF NEURASTHENIA AND ITS
TREATMENT,

in which he said that ever since Beard used the term neurasthenia; and Van Dusen directed attention to a group of symptoms so named, the profession had been struggling to map out a definite set of symptoms to be thus classified, and in his opinion we had as yet but poorly succeeded. Althaus, of London, protests against the term and Gowers says that nervousness covers the conditions. Different writers give different illy defined symptoms and subdivide them into cerebral and spinal symptoms, some observers even finding varied local conditions which they characterize as neurasthenia. There is one thing upon which authors are agreed, namely, that this group of symptoms indicates disease of some part or every part of the nervous system; that there is a marked defect in the nutrition of the cerebro-spinal axis, giving an almost endless variety of symptoms difficult to classify. The changes noted in the patient come on gradually. These changes were described and which occur in cases of neurasthenia. The author believes that neurasthenia as a distinct disease does not exist. It was simply a popular term among the laity, and many a young woman had become useless in the world of action because she thought she had neurasthenia. Physicians were to some extent to blame for encouraging this popular delusion.

Under the head of treatment the author expatiated upon elimination, food and environment. A systematic course of hydrotherapeutic treatment in addition to medication was essential to the best results, particularly with reference to elimination through the skin. Recumbent rest and active exercise he prescribes in frequent alternations for every day with methodical regularity. For stimulation of the nerve centers a hot fomentation of the entire spine, or the alternation of the fomentation and ice to this entire region produces admirable results. The patient's environment should be pleasant, agreeable and often unhomelike.

DR. JAMES T. WHITTAKER, Cincinnati, Ohio, delivered the Address of Section One. He selected for his subject

CRYPTOGENETIC SEPSIS.

The author said that the terms pyemia, septicemia, sepsis, septic pyemia, are variously employed by different authors. There is no longer support for the different terms. Pyemia was the term first employed. It was a useful term because it expressed a poisoning of the blood by pus and connected this poisoning with a pus center. So distinct was this connection that the people understood it in the common term "blood poisoning." But the mere presence of pus in the blood does not necessarily produce blood poisoning. In one sense there is always pus in the blood, that is, there are white blood corpuscles, leucocytes, and these corpuscles accumulate in leucocyto-

sis to constitute a protective process. Pyemia is now generally understood to mean infection of the blood as indicated by multiple metastases, in the absence of any central depot of suppuration: whereas, septicemia is used to express the infection of the blood in which there is a decided depot in the absence of demonstrable metastases. But it is plain to see that these are distinctions without much difference. The term pyemia having served its purpose should in the opinion of the author be retired altogether. Lines may be drawn between septic intoxication and septic infection, understanding by intoxication poisoning from the absorption of chemic matters, ptomains, toxins, and by infection poisoning by the direct penetration of bacteria. But in practice these various poisonings are so commingled as to be inseparable in most cases. Modern medicine, which is based upon etiology, prescribes that parentage alone should give the name to a disease. All the symptoms which have been grouped under the terms pyemia, sepsis, septicemia, etc., are produced by the same cause, namely, by the pyogenic microorganisms. The speaker believes it would much simplify matters to retain the term septicemia to express the whole train of symptoms caused by the infection of the blood with pyogenic microorganisms, whether bodily as by bacteria, or chemically, as by toxins.

It is believed at the present day that rheumatism is caused by microorganisms closely allied to, if not identical with, the microorganisms of pus. Goldscheider demonstrated bacteria in the serous exudation of pleurisy, which he believed to be due to rheumatism. Upon cultivation these microorganisms turned out to be staphylococci. Sahli developed cultures of a microorganism from the exudation of endocarditis, which turned out to be the staphylococcus citreus.

DR. WHITTAKER made the point that many of the lighter forms of disease, which have been vaguely described as rheumatism, as malaria, as incipient tuberculosis, as la grippe, as a bad cold, are cases of light infection with septic matter in which the microorganisms of sepsis may be found in the blood, and that individuals, the frequent subjects of these diseases, are carrying about in them manifest or more especially concealed depots or colonies of septic microorganisms.

The term cryptogenetic sepsis is really reserved for the cases in which the source eludes detection during life. Sometimes it may be disclosed upon the postmortem table, and such cases have found explanation in suppurating bronchial glands, mediastinal depots, prostatic abscesses, latent endocarditic processes. The avenue of entrance is found in any possible injury of the skin and mucosa, wounds of operations, etc.

The outside origin of sepsis is clearly indicated in the septicemia of the newborn. According to Epstein, septic infection of the newborn occurs, 1, at the umbilicus; 2, from the mucous membrane of the mouth, and 3, from the mucous membrane of the female genitals.

The prognosis of cryptogenetic sepsis is always serious, but depends upon the virulence of the poison, the height of the fever, the weakness of the heart, the gravity of the nervous system and the character of the complications.

The treatment may be dismissed in a few words. The prophylaxis depends upon an increase in the general habits of cleanliness, the greater frequency of ablutions and more care for higher sanitation. People should be informed of the possibility of infection from the most minute injuries and should be warned against handling decomposed substances or from ingesting decomposing foods. The author said nothing concerning the specific treatment of septicemia, for the reason that the entire subject was still too new to formulate definite conclusions. Finally, he hoped some young bacteriologist in our country would find in this subject an incentive for further study.

DR. J. O. DECOURCEY, St. Libory, briefly outlined the medico-surgical treatment of anthrax.

DR. J. E. SUTTON, Canton, read a paper on "Tedious Labor." The object of this contribution was to assist in bringing about a better understanding among general practitioners of the symptoms and difficulties attending occipito-posterior presentations.

DR. HENRY P. NEWMAN, Chicago, followed with a contribution entitled

FACTS, FADS AND FALLACIES IN GYNECOLOGY.

Less than a century ago the name gynecology was unknown, and the principles governing the treatment of the diseases of women were shrouded in darkness. The author briefly traced the steps in medical progress—anesthesia, anatomic and pathologic discoveries, and greater clinical advantages, which he said were all causes which had made possible the high state of advancement attained in the treatment of diseases of women.

Our predecessors in practice had their hobbies and their prejudices and fought for them, not as in the fraternal discussions of

our day, but with bitter pen and bloody sword. Perhaps the amenities of modern professional life were to blame for the rapid spread of some prevalent fads. The well-nigh perfect methods of gynecologic and obstetric work had enabled physicians to snatch thousands of women from premature graves, or relieve them of the numberless ills to which female flesh is heir, but have we thereby made womankind the gainer? The question seemed like a paradox, but we must not forget that the true and ultimate aim of medical science was not to cure the individual or individual ills, but to raise the standard of health for all and make life the rich and gracious thing nature intended it to be. The evil conditions which call for the exercise of so much skill in gynecologic and obstetric practice are the outcome and the expression of nature's resentment against the perverters of her wise and beneficent laws.

DR. E. W. LEE, Chicago, read a paper entitled "Vaginal Atresia."

The following officers were elected for the ensuing year:

President, Dr. A. C. Corr, Carlinville.

First Vice-President, Dr. J. M. G. Carter, Waukegan.

Second Vice-President, Dr. T. J. Pitner, Jacksonville.

Permanent Secretary, Dr. John B. Hamilton, Chicago.

Treasurer, Dr. G. N. Kreider, Springfield.

Judicial Council, Dr. J. L. White, Bloomington; Dr. E. P. Cook, Mendota, Dr. D. W. Graham, Chicago.

Chairman, Section One, Dr. Jas. B. Herrick, Chicago; secretary, Dr. J. O. De Courcy, St. Libory.

Chairman, Section Two, Dr. H. P. Newman, Chicago; Secretary, Dr. E. W. Weiss, Ottawa.

Chairman, Section Three, Dr. O. B. Will, Peoria; Secretary, Dr. R. C. Matheny, Springfield.

Committee of Arrangements, Dr. Charles F. Wilhelmj, East St. Louis; Dr. H. C. Fairbrother, East St. Louis; Dr. J. W. S. Dyer, East St. Louis; Dr. W. H. McLean, East St. Louis; Assistant Secretary, Dr. J. L. Wiggins, East St. Louis.

Committee on Medical Legislation, Dr. J. W. Pettit, Ottawa; Dr. D. W. Graham, Chicago; Dr. J. B. Maxwell, Mt. Carmel.

Necrology and Biography, Dr. J. H. Hollister, Chicago, Chairman; Dr. O. B. Will, Peoria; Dr. E. J. Brown, Decatur.

Medical Societies, Dr. C. W. Hall, Chairman, Kewanee; Dr. J. A. Baughman, Neoga; Dr. W. R. McKenzie, Chester.

Committee on Medical History consists of all members of forty years' standing.

Committee to act jointly with Missouri Medical Society, Dr. E. P. Cook, Mendota; Dr. Geo. N. Kreider, Springfield; Dr. L. C. Taylor, Springfield.

The next meeting will be held at East St. Louis, third Tuesday in May, 1897.

American Laryngological Association.

Annual Meeting held at Pittsburg, Pa., May 14, 15 and 16, 1896.

(Concluded from page 1132.)

THE CONTROL OF HEMORRHAGE IN SOME OPERATIONS IN THE NOSE AND THROAT.

DR. A. COOLIDGE, JR., Boston, states that the first consideration in undertaking an operation under an anesthetic is the position in which to place the patient. The horizontal position with the patient on the table is often contraindicated by the danger of blood finding its way into the pharynx and larynx. For operations confined to the nasal cavity this may often be prevented by plugging the posterior nares as a first step in the operation. The Rose position with the head hung perpendicularly over the end of the table, although preventing blood from entering the lower pharynx is, to most operators, awkward and unsatisfactory. The Trendelenburg position protects the trachea from blood in thyrotomy and operations deep in the pharynx. The most generally useful position for operating in the upper respiratory tract is with the patient held sitting in a chair opposite the operator. By inclining the body well forward blood from the naso-pharynx and mouth flows outward, but it is absolutely necessary in using this position that there should be sufficient assistance to control the patient. It is therefore much easier in the case of children than with adults.

For the local control of bleeding where the bleeding vessel can not be found, compression offers the best means: styptics are to be avoided if possible, as being unreliable, a loss of time and irritating.

Hemorrhage from the nasal cavity can usually be stopped by plugging through the anterior nares, and ability to do this easily and quickly will give the surgeon confidence in attacking this part of the body. Hemorrhage in the naso-pharynx is controlled by filling the cavity with gauze from below, by the same method as is employed for plugging the posterior nares.

The amount of bleeding to be expected in the removal of a new growth or hypertrophied tissue depends both upon the size and number of the vessels entering the tumor, and the amount of contraction allowed by the structure of the intravascular tissue, as is shown by sections cut at right angles to their attachments. Adenoid vegetations, tonsils and myxomata seldom give rise to troublesome bleeding, whereas sarcomata and fibromata attached to the basilar process sometimes bleed copiously and persistently. The readiest method of controlling the latter is by immediate plugging of the posterior nares after removal and packing at the same time through the anterior nares. In the removal of adenoid vegetations the Gottstein curette, although attended with more bleeding at first, causes less loss of blood than the longer operation with the forceps.

In removing the tonsils with the tonsillotome there is a brisk flow of blood at first which generally subsides quickly, although in adults it may cause serious loss of blood. This can in most cases be prevented by the use of cold wire, if the patient is under an anesthetic, or by the use of the hot wire with the help of cocaine.

DR. F. I. KNIGHT gave a short résumé of the subject of

DYSPHONIA SPATICA,

and reported a case of an intermittent form of the affection, a condition which he had never met before. The patient, a clergyman, would speak in a normal voice for half of his sermon and then, presumably being tired, lapse into the characteristic high-pitched, jerky voice of dysphonia spatia. At his interview with Dr. Knight he spoke throughout it in a normal voice. Dr. Knight said it was the first patient of the kind he had ever seen, who did not betray his affection during the interview.

A CASE OF UNUSUAL LARYNGEAL GROWTH.

DR. J. W. GLEITSMANN, New York, mentioned the case of a patient, a Russian Jew, a street merchant, aged 38, who had been hoarse for one year, but had had no emaciation, pain, cough or dyspnea. Examination of the throat showed nothing externally. No enlarged cervical glands could be detected. Internally the pharynx appeared healthy. There was in the larynx on the right side a large almost snow-white mass, extending horizontally the entire diameter of the larynx from the anterior commissure to the arytenoid cartilage. It appeared to be located between the true and false cord and looked exactly as if a bunch of cotton had been inserted all along the ventricle of Morgagni. The surface was slightly corrugated and its free border a little irregular. The rest of the larynx presented no anomaly worth mentioning. The movements of the right side of the larynx were practically unimpaired and adduction of the cords was perfect.

With Landgraf's double curette a piece of the growth was removed, with only slight bleeding and no unpleasant reaction. Unfortunately the fragment removed was not cut deeply enough to reveal the microscopic structure and in about two weeks a larger piece was excised. The report thereon was as follows: "Papilloma durum laryngis," probably malignant and perhaps carcinomatous. It is composed of proliferated papillary mucosa covered with a thickened epithelial layer. The surface layer of epithelia presents itself as a bony covering; the underlying epithelial cells show marked proliferation with a splitting up of the nuclei. The submucosa shows a small-celled infiltration in consequence of connective tissue proliferation. The epithelial layer shows a tendency to invasion of the subepithelial tissue as in carcinoma.

The glands at the margin of the growth appear very much changed. The individual tubules or ducts should appear distinctly separate one from another, instead of which the cylindrical epithelium appears at certain points to merge from one duct to another. After the second operation the patient refused further treatment and the case was lost sight of.

Dr. Gleitsmann observed that allusions to whitish-looking tumors of the larynx are very scarce in literature. Fraenkel ("On Cancer of the Larynx," 1889) states that it is erroneous to suppose that in its earlier stages cancer of the cords produces hyperemia or inflammation. On the contrary, the carcinoma often presents a surprisingly white appearance. Semon also has suggested that an unusually snow-white color or grass-like appearance in tumors points strongly to malignancy.

A remarkable case of fibro-chondroma of branchial origin or so-called supernumerary ear, removed from the throat of an infant at six weeks old by Dr. A. W. De Roaldes. The case reported by the author is the most unique, and only one of a similar nature is on record in this country.

THE SEQUELÆ OF SYPHILIS OF THE NOSE.

DR. CHAS. H. KNIGHT said that the diagnosis of late syphilis of the nose is often obscure. The notes of a case of intranasal

tumor, pronounced a sarcoma for which excision of the jaw was advised, were given as an example. The patient developed a tibial node which, together with the nasal tumor, disappeared under constitutional treatment. Reference was made to the characteristic symptoms of syphilis when limited to the soft parts and to its much more serious consequences when invading the cartilage or the bone. The fact that syphilis is responsible for a certain proportion but by no means for all perforations of the septal cartilage met with was mentioned. When the bone has been attacked, two problems have to be met: 1, When and how to remove diseased bone, and 2, how to remedy resulting deformity. The author advocates conservatism in dealing with sequestra, unless they are quite detached and accessible. In case dead bone is firmly attached or embedded, or its limitations can not be clearly defined, or if it be located high in the nasal cavity in the ethmoid region, it must be approached with great caution. Loose sequestra of large dimensions may be conveniently removed through a large incision. The external deformity resulting from loss of the cartilage is often not noticeable, that from destruction of the skeleton of the nose is frequently hideous. The discussion of the treatment of this condition was limited to a description of what is known as the Martin platinum bridge and its modification and of the methods of its insertion. Several cases were referred to more or less in detail. The method is believed to be an excellent one with certain precautions. It is especially important that the active stage of syphilis should have been long passed and that the patient should have had radical treatment. Great care should be taken in the construction and shaping of the platinum bridge to avoid friction and pressure, and finally the dissection of the soft parts must be so wide as to obviate tension after the bridge has been put in place. The paper concludes with a reference to the use of a simple plate of platinum slipped under the skin of the dorsum of the nose, the dissection in preparing a bed for the metal having been carried on through the nostril, a much simpler method and one which may prove to be equally effective in conditions of moderate deformity.

ACUTE DISEASES OF THE LINGUAL TONSIL.

Dr. H. L. SWAIN, New Haven, Conn., said that if one was to judge by the amount written on this subject, it neither attracted or deserved much attention. If he has to judge by his own experience, which in the last three years had developed the fact that he must have overlooked many cases of acute trouble in this locality, the subject has been and was still being sadly neglected. In any case he had become convinced that acute lingual tonsillitis was often the cause of symptoms which were referred to other parts of the throat, simply because the latter were more frequently inflamed and more easily seen.

After some remarks on the anatomy of the parts, by which it was made evident that from the nature of the tissue and its surroundings acute inflammation would rarely assume the peritonsillar type, he went on to describe the symptoms of the various forms of acute lingual tonsillitis. He distinguished three varieties: the simple, the follicular, and the peritonsillar or phlegmonous. The symptoms were the same as in other acute diseases of the throat, modified by the difference in the locality affected. Especial stress was laid upon the cough, which is so often present in these troubles and persists long after the other symptoms subside. Very often one was led to blame the larynx in such cases when the lingual tonsil was at fault.

When the deeper tissues were affected, much severer symptoms arose, principal among which was the involvement of the epiglottis and glottis. In such cases life might become endangered and prompt and radical measures were necessary. Tracheotomy had to be sometimes performed.

In discussing the treatment he remarked, that in no acute throat trouble was there so evident and prompt effects produced by proper local treatment as in this. Repetition was necessary, but one uniformly had some reward for his labors. Anything that would reduce the swelling and inflammation was to the point. Glycerite of boro-glycerid applied to the parts and followed by a powder containing tannin and a small amount of morphia sulphate seemed to give as much relief as anything, to be assisted by frequent hot demulcent gargles. Systemic remedies were indicated in the same way as in other forms of tonsillitis. He closed the paper with a short history of a case of abscess of the lingual tonsil, which had slowly developed upon an attack of faucial tonsillitis. It had been ushered in by a short attack of edema of the glottis. The abscess had formed close to the ary-epiglottic fold and broke well back toward the arytenoid cartilage.

TREATMENT OF ACUTE LARYNGITIS AND BRONCHITIS.

Dr. THOMAS HUBBARD, Toledo, called attention to the essen-

tial features of acute inflammation of the middle respiratory tract. Hyperemia of the bronchial membrane, with more or less swelling, produces a condensation of the cellular elements, since the same number of epithelial cells occupy smaller area in proportion as the caliber of the tube is lessened. This is one reason why it is so difficult to re-establish mucous flow, the outlets from the glands being closed. Retained mucous ferments become acrid and irritating whether within the substance of the membrane or in the tubes.

Inflammation of throat and glands is often gradually progressive. The larynx may be in stage of resolution and bronchi in first acute stage, and vice versa, the acute stage in the larynx being prolonged by constant reinfection from diseased throat foci. Treatment must be directed more in accordance with the condition.

The primary indication is to establish a free flow of mucous. Apomorphia in 1-30 gr. doses repeated every two to four hours is the best relaxing expectorant. Except in very severe cases and in debilitated subjects it is rarely necessary to follow with stimulating expectorants. Where relaxing expectorants are judiciously administered there is much less indication for opiates. All forms of abortive treatment are deprecated.

REPORT OF A CASE OF SQUAMOUS EPITHELIOMA OF VELUM PALATI CURED BY INJECTION OF CAUSTIC POTASH.

Dr. THOMAS HUBBARD, Toledo, stated that for more than a year, the tumor, of flat tubular type, situated partly in velum and partly in anterior pillar of fauces on the right side, had resisted internal and local treatments at the hands of several practitioners and specialists. Cocain habit was established. In August, 1894, he was on the verge of collapse from malnutrition, his sole diet being milk and ice cream in limited quantity. Cocain habit was first cured and he improved somewhat, but nothing relieved the pain incident to deglutition. Injections of caustic potash by curved platinum needle, destroyed a conical shaped tumor mass. Lesser injections were repeated wherever proliferating epithelial growths were seen around the edges. Cicatrization was rapid and so was the improvement in general health. He gained forty pounds in two months. There are no signs of return now, nearly two years after first injection.

A CASE OF PERICHONDritis OF THE LEFT CRICO-ARYTENOID JOINT, FROM AN UNUSUAL CAUSE.

Dr. H. S. BIRKETT, Montreal, referred to a young man who contracted gonorrhea and was attacked by inflammatory rheumatism during the course of this trouble affecting the left knee, ankle and left shoulder joints, and with the onset of this he developed a soreness and difficulty in swallowing, situated altogether at the left side of the throat. Upon examination the mucous membrane over the left crico-arytenoid joint was swollen and edematous. The ary-epiglottic fold on that side was not swollen. The vocal cords were white in color, and the movements of the left one, that of adduction and abduction, were decidedly slower than those of the right. Pressure over the affected joint outside was very painful. The voice was hoarse. The treatment consisted in constant applications of Leiter's ice coil which afforded the patient a great deal of relief. The condition was regarded as one of acute rheumatic affection occurring in the course of an ordinary gonorrheal rheumatism.

A paper on "Catarrhal Laryngitis," was read by Dr. C. C. Rice, of New York.

SELECTIONS.

A Method of Preventing Thirst after Celiotomy, with a Study of the Urine.—An abstract of a paper read before the Ohio State Medical Society during the late meeting at Columbus, by Dr. W. H. Humiston, of Cleveland. The patient is given the usual preparation for celiotomy, *i. e.*, diet, baths, cathartics, etc. For three days prior to the operation, the patient is required to drink a quantity of hot water not exceeding one pint an hour before each meal and on retiring, thus drinking about two quarts of water during each twenty-four hours, the last pint being taken three hours before the time appointed for operation. Particularly during the day previous to the operation while the patient is restricted to a limited amount of liquid nourishment, and the bowels are being unloaded, should the water be given. Thus is restored to the system the large loss of fluid occasioned by the free catharsis, with the satisfaction of having the patient pass the ordeal of the first thirty-six

hours succeeding the operation in comparative comfort, with no thirst, a moist tongue, an active renal function and a full, strong pulse. Also catheterization is rarely required. A tabulation of twenty-four successive cases in which a careful daily record of the urine was taken, gives the following results: The average total quantity of urine voided during the first twenty-four hours after admission to the hospital, was 29 fluid ounces, the average total solids amounting to 477 grains. During the twenty-four hours preceding the operation 30 ounces were passed containing 491 grains of total solids. The average quantity of urine voided during the first twenty-four hours succeeding the operation was 31.5 ounces, containing an average of 972 grains of total solids, and during the second twenty-four hours 25 ounces were passed with 680 grains. The doctor believes that the average total quantity of urine voided during the first twenty-four hours after admission is above that of the ordinary gynecologic case, but is explained by the fact at the first consultation he advises the use of at least an ordinary amount of water together with the administration of the ordinary diuretics, especially the potash salts and digitalis. Attention was called to the enormous increase in the amount of total solids eliminated during the first twenty-four hours after the operation over that of any preceding day.

Sanitary Burial.—The *British Medical Journal* reports the proceedings of a recent meeting of the Burial and Funeral Reform Association of London, at which papers were read by Sir Seymour Haden and Dr. Poore. "The former stated that for the last ten years he had been burying animals, large and small, in the park attached to his house. By digging them up and examining them at intervals varying from one to five years, he found that, buried at the depth of $4\frac{1}{2}$ feet, the depth required by the Government for the burial of human bodies, an interval of from three to four years was necessary for complete resolution; buried at the depth of 1 foot, a year and a half had proved sufficient for the larger, and a year or less for the smaller animals. On the other hand, a body not buried at all, but simply laid upon the ground with a covering of earth a foot thick over it, had completely disappeared (the bones excepted) in a year, the mound of covering earth, which had been sufficient to prevent all smell, retaining its shape, but when it was pressed with the foot, proving to be hollow. The body had thus returned to the atmosphere in the shape of oxygen, hydrogen, carbon, and other perfectly harmless products necessary for the nourishment and growth of plants. He (Sir Seymour Haden) was amazed at the folly, not to say impiety, of any attempt to beat this provision of nature. Dr. Poore, in his paper, contended that if a body was buried in such a manner as to further in every way its complete dissolution, the land would be ready after due interval of time to receive a second body, and that if the cemetery were systematically and sufficiently planted, the earth would be purified and the air around freshened by the green leaves of a flourishing vegetation. The power which scientific burial gave of using the same ground repeatedly after due intervals of about ten years, abolished the fear which had been expressed with regard to the amount of ground allotted for burial purposes. An acre of land would prove an ample area for a burial ground in perpetuity for a population of 10,000 persons. Such a burial ground would prove a decided benefit to the living as supplying in the midst of human habitations a breathing place which is so essential to the general well-being."

Tic de Salaam.—Dr. Joseph Collins writing editorially for *Pediatrics*, says that he finds no reference to this form of epilepsy in any of the English text-books, either under the name at the head of this paragraph or under any other. The synonyms, chorea nutans, salaam convulsions and chorée salutatoire are almost solely to be found in continental books or

journals. In respect of its occurrence in the field of American neurology, Dr. Collins says: "In the forms usually observed the disease is made up of a series of rapid, oscillating movements of the head and superior part of the body (spasmus salutans), which occur with a rapidity varying from ten to thirty times per minute. In some instances, during the height of the attack, the upper extremities are shot into the air, and for the moment remained fixed, while the eyeballs are rolled up, and the face has a fixed, non-expressive appearance. Whether or not consciousness is entirely lost during this period can not be said with certainty, first of all, because of the tender age of the patient, and secondly, because the rapid, fluctuating movements prevent the patient from answering or communicating. In marked contrast to the ordinary epileptic convulsions, whether they be of the 'petit mal' or 'grand mal' form, is the absence of any warning, and the rapidity with which the little sufferer regains his composure after an attack, that is, there seems to be none of the customary drowsiness, stupidity and desire to be left alone, as after an attack of epilepsy. Apparently there is no tendency to failure of mental development, or loss of what psychic faculties the child may have already obtained. The number of attacks with the patient may have in twenty-four hours varies from a dozen up to fifty or sixty, each attack lasting from one to three or four minutes. The phenomena have all the characteristics of a motor explosion or liberation of energy. Their occurrence is brusque, a rapid cessation between each twitch and an abrupt departure. The consensus of opinion of those who have seen most of this condition is, that the disease is a modification of the 'haut mal,' and the treatment which seems most serviceable is the treatment applicable to that form, namely, the persistent administration of bromid of potassium, with the occasional administration for a few weeks of minute doses of opium, while at the same time persistent attention is directed to the regulation of the alimentary and emunctory functions."

The Ultimate Effects of High Temperatures Upon the Blood and Tissues.—The *British Medical Journal* quotes from Werhowsky experiments upon rabbits. He used a large, well-ventilated thermostat of Lautenschlager, the body temperature of the animals being raised by increasing the temperature of the surrounding air, the experiments lasting from two to twenty-nine days. He found that when the temperature of the air reaches 37 C., the animals become at first restless, but later lie flat on their belly, respiration being quickened. After a few hours their temperature rises 2 or 3 C., but sinks again on the following day, and remains afterward at 39 to 40.5. If the temperature of the air is raised to 38.5 or 40, the body temperature rises to 41 or 42. After the second day the animals are quiet, and behave normally in all respects. The amount of urine is lessened, and albumin appears only toward the end of a long experiment. Of six animals, four died and two were killed on the fourteenth and twenty-seventh day of the experiment. Constant changes: 1, emaciation; 2, progressive diminution of amount of hemoglobin in the blood, by as much as 30 per cent. in a long experiment; 3, diminution of the total number of red corpuscles, but often not in the same proportion as the hemoglobin; 4, the only change in the red corpuscles is an increase of the small forms; 5, the white blood cells; there is an increase of the large single nucleated cells, and of the polynuclear pseudoeosinophile cells, and a diminution of the small single nucleated leucocytes; 6, corresponding to the decrease of hemoglobin, there is an enormous increase of hemosiderin in the medulla of bones and in the spleen; 7, no hemosiderin is found in the liver, unless death occurs early through great overheating; 8, the kidneys contain at most only a trace of iron; 9, the glands: (a) The liver cells are granular, sometimes vacuolated, and full of fat globules. It is questionable if this fatty degeneration can be produced by a short exposure to heat,

as, although present in an animal which died on the second day, whose temperature had been raised to 42 C., it appeared to be of older standing than this. (b) The kidneys remain unchanged for a long time by moderate temperature, but at last suffer from fatty degeneration mostly affecting the cells of the convoluted tubes. High temperatures cause a loss of the nucleochromatin and complete destruction of the nucleus. 10, the muscular cells of the heart undergo fatty degeneration later; 11, voluntary muscles and those of the intestine are always unaffected; 12, hemorrhages into the alveoli of the lungs were found in the animals which died, but the lungs of those killed were normal.

The Plague of Mice in Russia. Bacterial Experiments for Their Extermination. The *Consular Reports* for April contain a long contribution on the above subject, collated from a number of Russian governmental sources. Southern Russia and Siberia have during the last three years been the scene of the rise and fall of a pest of mice. In some places the destruction of property by the rodents was a serious item in the sum total of the general misery of the peasant class. Regarding the bacteriologic work undertaken for the extermination of the animals, the reports from the laboratories are indicative of success but not conclusive: at all events the closing up of the plague seems to have been chiefly due to the spread of infectious disease among the mice, but whether this was caused by the bacillus typhi murium or in some other way, no positive statement is made. The Governor of Cherson includes the following in his report:

1. It was particularly noticed that field mice had multiplied and that the number of house mice had largely increased.

2. The warm winter had without doubt favored their propagation, but probably the main cause consisted in the large quantity of cereals which had remained all over the province, in the shape of thrashed grain as well as in stacks.

3. It is also certain that the mice increased on the spot, but, according to the observations of some landowners, the mice were noticed to move from east to west. This gives reason to believe that they immigrated from neighboring provinces and occupied the territory of the entire province.

4. The reports regarding the extraordinary increase of the mice date from the spring of 1894, but its commencement dates back to the autumn of 1893: of late, the mice perish from some disease which is not as yet defined, but to determine its nature certain measures have been taken by the Department of Agriculture. It is not possible to estimate the extent of damage caused by mice; all the more so, because they are accompanied by rats which not only devour grain and other produce, but even destroy village buildings.

5. Up to the present, the population have used various domestic remedies for the extermination of the mice, beside which, with the assistance of the rural administration, it was determined to poison the mice with Professor Loeffler's cultivations of typhi murium, as prepared by the Odessa bacteriologic station and the Cherson bacteriologic laboratory. This cultivation of typhi murium shows its effect upon the numbers of mice not sooner than three to four weeks after its use. In June, 1894, the Department of Agriculture sent to the Province of Cherson, Dr. Merezhkovski, the assistant of the manager of the bacteriologic laboratory of the department, to carry out experiments of exterminating the mice by means of the cultivation of the bacillus discovered by him. The experiments carried out by him in the agricultural school of the Cherson rural administration gave good results, and in October they were extended to the estate of G. L. Skadovski, a landowner, where they were superintended by a special committee: on the sixth day, the mice began to perish of the cultivation of Dr. Merezhkovski, and on the ninth day this attained considerable dimensions and the mice were reduced

to their normal number. In April, 1895, the department sent out bouillon with the cultivation of Dr. Merezhkovski, but there are no reports as yet to hand concerning the results. The United States Consul at Odessa adds that when the army of mice swarmed over houses and huts through the country, the dogs and cats refused to molest them, and says "An incident which came under my own personal observation is not without interest. While I was waiting for a train at a small station on a branch line of the Southwestern Railway, a clergyman, with very long hair and beard, who was walking up and down the platform, stopped for a moment and raised the end of a canvas which served as a cover for a large quantity of wheat which was awaiting shipment. In an instant a mass of mice sprang at him and his beard, hair and cloak were literally alive with them. To brush them off was a matter of some time, and when my fellow traveler at length thought himself free, he was dismayed to find a mouse in each of his trouser pockets." Doubtless, all bacteriologists are familiar with the experiments of Loeffler, Lazare and Merezhkovski; but it may not be amiss to mention that, besides certain morphologic distinctions the differences between the bacillus typhi murium of Loeffler and the bacillus derived from mice by Merezhkovski consist mainly in this, that the mice die sooner when infected with Merezhkovski's bacillus than with that of Loeffler. Experiments with the infection of mice by means of Merezhkovski's bacillus were carried out by himself in his laboratory. As regards the bacillus typhi murium of Loeffler, besides the experiments of exterminating mice in the fields carried out by Loeffler himself in Greece, similar experiments were made by several Russian laboratories, among others, by that of the Odessa bacteriologic station in the provinces of Cherson and Podolia. These experiments were made in the fields and in the places where there was grain in stacks, and gave satisfactory results. These cultures of Loeffler's bacteria are customarily sent out in tubes of agar-agar, where they can retain their vitality during the course of several months. The contagium of typhi murium presents itself in the shape of a gray film on the slanting surface of the jelly in the testing tubes. For the purpose of using it, the film must be mixed with water in which pieces of white bread are soaked; the transparent remainder of the contents of the tube must be distributed, together with the pieces of bread, in the localities where the mice prevail. The details of this manipulation are as follows:

1. A 0.5 per cent. solution of table salt in water (one teaspoonful of salt is taken for five glasses of water) is prepared by boiling it for twenty minutes and subsequent cooling.

2. The testing tubes are filled with this water to one-half, the film is carefully scraped off by means of a little stick, and the liquid contents of the tube are poured out into the prepared solution; to five glasses of water, three testing tubes are taken.

3. In the liquid thus obtained, pieces of bread are soaked and distributed over the places indicated. The mixed contagion must be used immediately. Before using the cultures, it is indispensable to test their virulence on mice.

Mexican Criticism of Pullman Cars.—Forcible indeed are the denunciations of sleeping cars in the *Gaceta Médica de México* for May. The suffocating heat, the lack of ventilation and illumination, the unsanitary closets, are mentioned as if our Pullman sleepers, of which we Americans have been so proud, were utterly and entirely behind the times. It says that at least the improvements in new modern hotels should be introduced into them, air supplied incessantly and gradually, electric lights and strict sanitary arrangements in the closets, drinking water, &c. The precautions to be taken to prevent infection from disease are discussed also, and a radical reformation urged in many directions under the advice of experts.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the ASSOCIATION living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JUNE 13, 1896.

CARDIAC SURGERY.

The recent remarkable case of CAPPELEN seems sufficient excuse for directing attention to some details of cardiac surgery. In the first place it may be noted that wounds of the heart or pericardium are by no means inevitably fatal. Thus STEUDENER relates a case of a man who was shot through the heart and the bullet ranged backward through the spinal cord, causing paraplegia. Death occurred in fifteen weeks, evidently more from the latter cause than from the heart wound. In WEST's case a man received a stab from a shoemaker's knife. After remaining in the hospital for a month he was discharged, and died from tuberculosis four years afterward. PROF. CONNER of Cincinnati, relates a case¹ of a boy, aged 15 years, who was shot from behind. Pneumonia, endocarditis and pericarditis developed, and after thirty-one days the patient was able to walk. A valvular lesion remained as a result of the endocarditis, and death occurred three years and two months afterward. These cases were confirmed at the necropsies.

Even more remarkable are the cases reported by MM. VELPEAU and BRUGNOLI. In the former's case a man of 50 came to the necropsy table with a history of having received a stab in the left breast from a table knife some nine years previous. At the examination scars were discovered both in the pericardium

and in the right auricle, with adhesions between. BRUGNOLI records the case of a man who, after receiving a stab from a knife, was able to resume work in seventy-eight days, and lived for nineteen years. The necropsy disclosed an enlarged heart, an adherent and calcareous pericardium, and old scars in the right ventricle and septum, with a split mitral valve.

The heart is an organ that sometimes tolerates foreign bodies very well, and again a slight injury gives rise to a fatal issue. Among foreign bodies found in this organ besides bullets and needles, which are the most common, are splinters of wood, fish bones, etc. Even the ubiquitous hat pin has been discovered (LANGIER). Bullets have been found encapsulated in the heart for many years; in the right ventricle six years (LATOUR); in the wall of the ventricle for twenty years (BALCH); and for no less than fifty years in the pericardial sac. It must be observed in passing, however, that these cases refer to the old fashioned round balls; few conical balls will be stopped by the heart, and still fewer, if any, of the most recent projectiles of small caliber and extreme penetration.

The extent of the wound does not seem to bear any decided relation to the duration of life, for while STEINER's experiments seem to prove that simple puncture by a needle is not very dangerous, yet several cases are on record of immediate death resulting from needle wounds, either accidental, homicidal or otherwise. Again, in the cases where recovery took place, as previously mentioned, the damage was much greater than any that could be inflicted by a needle. In BRUGNOLI's case the mitral valve was implicated; in CONNER's, one cusp of the aortic valve; yet the patients survived for years.

The causes of immediate death after heart injuries are two in number, nervous and mechanical. First, by interference with the ganglia presiding over the movements of the organ, and second, by the effusion of blood into the pericardial sac, thus compressing the organ and hindering its action. For the former complication surgery is of no avail. In the latter, however, it would seem that evacuation of the fluid or clotted blood might be followed in many cases by favorable results.

Although paracentesis of the pericardium was first proposed by RIOLAN over two centuries ago (1649), it was not until late in the present century that it was actually put into practice. ROBERTS reports over 40 per cent. of recoveries after paracentesis or incision, and bearing in mind the usually fatal ending of the affections requiring this operation, the figures are highly encouraging. Possibly these favorable results have encouraged surgeons to advocate suturing bullet and stab wounds of the pericardium and heart. PARK, of Buffalo, we believe, is the latest of these.

It has remained for CAPPELEN to put this sugges-

¹ Cincinnati Clinic X, p. 253.

tion into practice. The patient was a man of 24, who had received a stab from a knife some hours before admission. On entrance he was unconscious, no pulse could be felt, the heart sounds could be heard, but no impulse was perceptible. The wound was punctured, not bleeding, one centimeter long, and situated in the left fourth space, parallel with the rib. After an injection of camphor the patient began to breathe and the pulse could be felt. The left side of the chest did not move. Under chloroform the wound was enlarged, and the fourth rib was resected. The left lung was compressed by an accumulation of blood in the pleural cavity, partly fluid, partly clotted. After this was evacuated the lung expanded and was found to be not wounded. The third rib was now resected and a wound which was bleeding freely, was found in the pericardium, one centimeter long. The pericardial sac was found to be filled with coagulated blood, and after enlarging the wound in the pericardium, another one measuring one centimeter in length was found in the left ventricle, which caused the hemorrhage. This wound was sutured and an artery tied, when the bleeding ceased. The account of the operation states that the suturing was rendered extremely difficult by the rhythmic movements of the lung, which covered the field of operating and obscured it, and by the contractions of the heart, which however were quiet and regular. The suturing was accomplished by bringing the needle half way through during a contraction, then dropping it, and after a second contraction bringing it completely through. After the operation the patient's pulse was very rapid and feeble, but improved after saline injection. The patient sank gradually and died two and one-half days later. The necropsy showed a wound of one of the large branches of the coronary artery; the wound had healed partially, but there was a beginning pericarditis and various bacteria in the exudate. While death ensued, yet the fact that the patient lived for over two days, and that no operative measures could be instituted for some hours, shows that in more favorable cases recovery will follow.

FISCHER's statistics² prove that the most important parts of the heart functionally, the ventricles, are much more liable to wounds than the auricles, 257 wounds of the ventricles against only 31 of the auricles, a result which might be expected from the smaller size and less exposed position of the latter. Again, the great urgency of similar operations may preclude as thorough aseptic precautions as those in other measures of less expediency. However, in view of the foregoing facts the opinion seems warranted, that "the citadel of life" itself will no longer be exempt from the incursions of the surgeons.

HOSPITAL PRACTICE REQUIREMENT FOR ARMY MEDICAL SERVICE.

The progress of medical education keeps pace with that of modern medicine and surgery. As the fields of knowledge become extended, the necessity for a change in educational methods from the lectures and text books of the past to the laboratory work and practical teachings of the present, was recognized by our leading colleges. One after another of these institutions are extending their courses, increasing their years of study, and providing educational facilities that their graduates may be equipped satisfactorily at the outset of their professional career.

The Medical Department of the Army since its organization during the War of the Revolution has filled its ranks by selection of the fittest. A board of medical officers selects its approved candidates from those who come forward for examination. The members of this board, jealous of the good repute of their corps, allow admission to none whose professional attainments are not such as to promise a satisfactory future record. This has given the army medical officer in the past an unquestioned professional standing; and it is the evident intention of the present administration of the Medical Department that this status shall be preserved. Immediately after his appointment as Chief of his Corps, SURGEON GENERAL STERNBERG established an Army Medical School in which those who had just entered the service received special instruction in military medicine, surgery and hygiene, and particularly in practical laboratory work. The facilities of this school were available also for such officers of older date as were able to take advantage of them. At the same time he provided opportunities for professional improvement to those officers who had been isolated at frontier or interior posts far from medical centers. He gave them in rotation, as they neared the period of their examination for promotion, temporary assignments to duty as attending surgeons in cities where they could attend society meetings and lectures, observe the practice in large hospitals and study specialities in which they were interested. Lastly, in a new edition of a circular of information to candidates who desire to enter the service he has taken a step which will raise the standard of medical qualifications considerably. Former issues of this circular stated that hospital practice in medicine, surgery and obstetrics was important; but the present issue announces this hospital practice as essential. The candidate must submit the evidence to the board that he has had a year's hospital practice. Hospital clinics and dispensary practice embraced in the college curriculum do not satisfy the new requirements. The candidate must have been a resident or interne of a hospital for one year.

It follows that the practical result of the new re-

quirement will be to impose upon candidates a year of hospital experience or of practice equivalent to this, in fact a year of special preparation for the ordeal of the examination. This will bring forward a higher grade of candidate than formerly. The number of candidates and the percentage of unsuccessful candidates may be lessened, but the spirit of competition will be intensified and the Department will get the best men. That no intending candidate may be excluded from examination on account of age in consequence of the extra year of preparation the maximum limit of age at entrance has been raised from twenty-eight to twenty-nine years.

THE RELATIONS OF THE SEXUAL ORGANS TO THE DEVELOPMENT.

The apparent connection between the conditions of the sexual organs and growth in certain directions, are facts of common observation, but certain of them are taken up and treated rather suggestively by M. HENRY MEIGE in a recent issue of the *Journal des Connaissances Médicales*. He had already studied certain phases of these phenomena in a previous memoir on "Infantilisme et Féminisme," in which he pointed out that a certain degree of skeletal malformation was of frequent occurrence with the characteristic corporeal habit associated with congenital atrophy of the genital organs. Here, however, he calls attention to the more pronounced abnormalities that are sometimes observed, the frequent immature stature and the occasional giantism. Even in those who have been purposely or accidentally emasculated these are observed, as in the case of the Egyptian eunuchs observed by LORTET, in whom the excessive stature was due to the length of the legs, the thorax and trunk generally not exceeding the usual normal size. This corresponds with what is seen in the ox as compared with the normal bull, and M. MEIGE suggests as an explanation that the loss or atrophy of the sexual organs entrains the atrophy of the corresponding spinal cells, and the vascular supply of the cord being undiminished, the other nerve centers in the same region controlling the nutrition of the extremities are unduly benefited, with the result of the excessive development observed. For the changes occurring elsewhere in the body, somewhat similar but more general explanations are supposable, if one wishes to go farther into the domain of hypothesis.

The diseases of the sexual organs may also act in these directions, as well as the defects of development or the mutilations. M. MEIGE quotes in this connection a recent observation of SACCHI (*Rivista Sperimentale*, 1895) of an excessively developed boy of nine and a half years, with beard, male voice, precocious intelligence and disposition, pronounced sexual appetite, etc. The left testicle was enormously developed, 10 centimeters in diameter, and the right testi-

cle atrophied. Orchidectomy was performed on the left side and an epithelial parasitic growth discovered. Within a month a change began to be observed; the hairy growth of the face and elsewhere began to disappear, the voice became childish, the abnormal sexual precocity was lost, the intelligence and muscular strength diminished, the right testicle increased in size and the individual became in all respects more like a normal boy of his age.

According to SACCHI, this infantile giantism is to be accounted for by an abnormal influence of the parasitically excited testicle (probably through an increased secretion) on the general growth of the organism. However this may be, the observation is a very remarkable one and shows almost like an experimental demonstration the relations of the sexual organs to the general and special development. M. MEIGE further refers to the notable but irregular changes that are often observed to occur at puberty, causing what might sometimes be called a transitory acromegaly of the pubescent epoch. Development, which is as a rule excessive at this period, may be of certain portions more than others in a most surprising way and proceed, as it were, by jerks in different organs in succession. These phenomena are unnoticed because they are so common, but they have an important physiologic suggestiveness and significance, and are therefore more worthy of careful study than seems to be generally appreciated. The possibilities of experimental investigation in this direction are, moreover, not exhausted; there is an extensive field still open for research.

The pathologic side of the subject is also worthy of careful study. The various conditions of imperfect sexual development probably have a serious reaction on the vitality of the system as a whole, and make it the easier victim of noxious germs. A relation between infantilism and tuberculosis has already been suggested and supported by considerable clinical evidence.

Nowadays, when so much blind work is done in the way of extirpating important sexual organs on theoretic and probably often insufficient grounds, the necessity of a careful and thorough study of their relations to growth and general vitality is or should be apparent.

THE CHEMIST A PROFESSIONAL MAN.

Although the study of chemistry is the study of a science, yet the supreme court of the United States holds that a chemist who occupies himself in the practical use of chemistry, as his services may be demanded, may certainly, at this time, be fairly regarded as in the practice of a profession. He is none the less a chemist, and none the less occupied in the practice of his profession because he limits himself to a particular branch of chemistry, as, for

example, that which is to be applied in the course of the scientific manufacture of sugar, any more than a lawyer would cease to practice his profession by limiting himself to any particular branch thereof, or a doctor by confining his practice to some specialty which he particularly favored and was eminent in. Neither does the fact that he has agreed to sell his time, labor and skill to one employer and in one prescribed branch of the science, in the least militate against his being a professional chemist, nor does it operate as a bar to the claim that while so employed he is nevertheless practicing a recognized profession. It is not necessary that he should offer his services to the public at large, nor that he should hold himself ready to apply his scientific knowledge and skill to the business of all persons who applied for them before he would be entitled to claim that he belonged to and was actually practicing such profession. He may confine his services to one employer so long as the services which he performs are of a professional nature. Such are the views expressed by the above court in the case of *United States v. Laws*, May 18, 1896, where it specifically decides that a contract made with an alien in a foreign country to come to this country as a chemist on a sugar plantation in Louisiana, in pursuance of which contract such alien does come to this country, and is employed on a sugar plantation in Louisiana, and his expenses paid by the party with whom he made such contract, is not a contract to perform labor or service as prohibited by the contract labor law, which excepts persons who practice a recognized profession.

CORRESPONDENCE.

Treatment of Typhoid Fever.

MONTCLAIR, N. J., June 2, 1896.

To the Editor: I have just read with great interest two able addresses in your issue of May 23, one from the pen of Professor Osler, and the other from that of Professor Quine, both delivered at the recent meeting of the AMERICAN MEDICAL ASSOCIATION. Both of these gentlemen pay their respects to the Woodbridge treatment of typhoid fever, and both seem inclined to sneer at the so-called pretensions of the advocates of this treatment. Dr. Woodbridge has fought out his own battle with great pluck and pertinacity, and if there be any virtue in his plan of treatment, every practitioner in America who reads the journals or attends the meetings of a live medical society, is sure to hear of it. He does not, therefore, need any defense nor even aid from me. But if one can read between the lines, both the eminent writers and teachers spoken of above are preparing to let themselves down easy, and adopt an antiseptic treatment of typhoid in selected cases. It may not be necessary to give the Woodbridge tablets in the prescribed Nos. 1, 2 and 3 order, nor may it be wise to allow solid food on the tenth day, nor to encourage the patient to resume his ordinary avocation as soon as that. But I believe that the antiseptic treatment of typhoid is superior to all others, including the Brandt treatment, and I believe, further, that so honest a gentleman and so thorough a student as Professor Osler will acknowledge that typhoid fever can be aborted just as soon as he begins

to use calomel or other mercurial in small frequently repeated, or large occasional doses in the beginning of the fever, and follows it up by some of the antiseptics that Dr. Woodbridge recommends, or by the chlorin water so strenuously advocated by Burney Yeo.

In all the discussions which I have recently seen of typhoid and its treatment, it has seemed very odd to me that I have never noticed any allusion to the classic paper on the subject by Dr. John Harley in Reynolds' System of Medicine. If any one will read that paper with an open mind, I am inclined to think that he will at least be persuaded to try mercurials in typhoid. It is not that the one-tenth of a grain of calomel every fifteen minutes will so saturate the economy that it will poison all the microbes which may be lodged anywhere inside the integument, but such a course of medication will assuredly set in motion the flow of bile, nature's intestinal antiseptic. And right here I would like to ask those who say that calomel is not a cholagogue, why it is that a five or ten grain dose of this powder, which is so bland locally, will cause alvine dejections which are so hot and acrid that they will excoriate the perineal integument? I know from long personal professional experience that the above phenomena will follow the exhibition of calomel, and the hot and acrid substance I have always called bile. Whether it is really bile or not, it would seem to be injurious to microbes. However, I believe that the physiologists now assure us that it is bile.

And this leads me to observe that a person who speaks of minute doses of calomel given every quarter or every half hour as harmless (as some one has done in one or both of the papers which have called forth these remarks), shows a deplorable lack of knowledge of the action of this drug. Two grains of calomel divided into twenty doses and one of these doses given every half hour, has "touched" the gums of a well developed man more than once in my practice. In Dr. Woodbridge's reports repeated instances are given in which sore mouth was produced by his No. 1 tablets. And a mild degree of stomatitis is just what Dr. John Harley recommends in the early treatment of typhoid. He also says (pp. 4, 8, Vol. I, Reynolds' Syst.): "If at an early period we succeed in producing a flow of healthy bile, with moderate action of the bowels, we may arrest further progress of the disease and restore the appetite." It is true that Dr. Harley objects to calomel, preferring some other mercurial per os or inunctions of blue ointment. But it is not probable that any one in those days thought of giving calomel in the minute doses which we now use with such good effect. Had the discovery of the typhoid bacillus by Eberth been known when Dr. Harley's paper was written, his pathology of the disease would have been different, but his history and treatment might have stood just as they are now.

Now, Mr. Editor, I have not written these lines from any reason except that I am just as anxious that the truth about the treatment of typhoid should be known to the entire world, as Professor Osler, Dr. Quine and Dr. Woodbridge are. And I believe that Dr. Woodbridge has the right theory of treatment. The details may be altered, as Dr. Quine suggests, and quite likely will be.

So far as the cold bath treatment goes, it has too many and too distinguished advocates, including particularly Professor Osler, for any one to sneer at it or pass it lightly by. Still, my conviction and I maintain that having studied the disease sufficiently to have settled convictions in reference to it entitles me to be heard—agrees with Professor Yeo, who says (*Amer. Jour. Med. Sci.*, June, 1894, p. 651): "With regard to the routine cold bath treatment of typhoid, for my own part, I am disposed to leave it, almost without comment, to those who like it. . . . The method that I advocate has yielded in my own practice and in that of others better results, and I therefore prefer it."

Very respectfully yours,

RICHARD C. NEWTON, M.D.

Our Mexican Confreres.

NEW YORK, June 2, 1896.

To the Editor:—In common with every reputable medical man in this country, I can only regret that Dr. David Cerna has felt it incumbent upon him, in your issue of May 30, to reply to certain unfounded reflections upon the medical profession of Mexico. Statements, such as those he seeks to confute, might better have been left unnoticed, the very refutation giving them an undeserved publicity. The creditable appearance of the Mexican members of the First Pan-American Medical Congress, convened at Washington in September, 1893, their dignified demeanor, the admirable papers they contributed to the transactions, their intelligent participation in the discussions in the several sections, and their interested and zealous attention to their duties as committeemen, etc., were matters of commendatory comment by their colleagues in the Congress from other American nationalities, who were appointed with them for the first time. To the members of the American Public Health Association, which is proud of displaying the triple escutcheons of the United States, the Dominion of Canada and La Republica de México, they have long been known as among the ablest and most progressive of their associates. Their names appear on every one of its important committees. Each State in Mexico and the Federal District have their representatives on the Advisory Council, with the States of our own Union and the Provinces of Canada. More significant than all, Dr. Eduardo Licéaga, President of the Superior Council of Health of the Mexican Republic, has been unanimously elected President of the American Public Health Association for the year 1896 and will conduct its proceedings at the approaching annual meeting at Buffalo, N. Y., September 15 to 18.

I have, however, no intention of entering upon the defense of a country which is known in international medical assemblies the world over through the professional achievements of Carmona y Valle, Rafael Lavista and Eduardo Licéaga, and which has swelled the ranks of the noble brotherhood of medicine with such men as Domingo Orvananos, Francisco Marin, the Arellano brothers, J. E. Moujâras, Luis Ruiz, Angel Gavino, Martinez del Campo, Gomes, Garcia, Macouzet, the eloquent Gregorio Mendizabel, and hosts of others who exemplified the typical physician. When the United States of America shall be able to boast of a National Board of Health as ably administered as the *Consejo Superior de Salubridad* of the Republic of Mexico, it will realize what Mexico has done for medicine, and what medicine is doing for Mexico.

ALBERT S. GIBON,

Medical Director United States Navy (retired).

8 West 127th Street.

PUBLIC HEALTH.

Population of Paris.—*Le Journal Officiel* announces that the census of March 29 records a total population of 2,511,955, a gain of 87,250 inhabitants since the last census of 1891, five years ago, an annual increase of 17,450.

Financial Distress Through Neglect of Vaccination.—The prevalence of smallpox at Gloucester has caused great financial distress, all outside trade having been brought to a standstill. Nevertheless the antivaccinist minority continue to hold public meetings and attribute the outbreak to one cause after another, to everything except the right cause—the neglect of vaccination.

Alcoholism in Belgium.—The Academie de Médecine de Belgique announces that it considers alcohol the most formidable pathogenic agent of modern civilization, while the facilities for procuring it are greater in Belgium than in any other country. It has recently passed resolutions urging the legislature to

wage a merciless war against this mortal enemy of society, as a measure was under discussion that would have increased the number of distilleries.

A Use for Patent Medicine Literature.—It is a favorite axiom of the optimists that everything has its uses. But it has remained for the New Mexico Territorial Board of Health to find a use for the patent medicine almanac. In a recently issued circular on the prevention of consumption, among other things, it is advised that "every person so affected should spit into some receptacle and should see that the sputum is soon destroyed by fire. About the house there is no better way than to spit between the leaves of patent medicine almanacs—to be had freely at all drug stores—and after a half dozen or more spittings burn the book."

The Horse Sickness of South Africa.—Another hindrance to British land-pillage has been the "horse sickness" of South Africa, concerning which the following information is given in the current issue of the *Press and Circular*: "This disease, which is one of the chief obstacles to the development (seizure) of large tracts of South Central Africa has been the subject of close bacteriologic investigation by Dr. Erdington, the Director of the Bacteriological Institute at Cape Town. He has had no difficulty in identifying the mycelium which causes the disease, but great difficulty in growing it, as it failed to develop in any of the usual media for bacillus cultivation. He has, however, found, strange to say, that the natural gum which exudes from the wild mimosa, growing in the district, is laden with the mycelia, which seem to thrive and propagate on it, and his conclusion at present is that the only effectual remedy for the disease is to destroy the mimosæ. There is an analogy for this in a sort of 'rust' that has been found to have its *habitat* on the leaf of the barberry tree, which affects corn, and which has been got rid of by destroying those trees wherever the 'rust' has appeared."

Scarlet Fever at the Paris Hospital des Enfants Malades.—Out of 239 cases received during 1895, there were fourteen deaths, half of which occurred almost immediately after arrival. The age averaged from 3 to 9, and the cases were less severe as the age increased. The disease was most prevalent in spring and summer; the complications were most frequent in autumn, with most fatalities in the winter. Forty-three per cent. were followed by complications: Otitis, suppurating glands, albuminuria, bronchopneumonia, secondary angina, etc., ascribed in large measure to the defectiveness of the hospital. The treatment was limited to a strictly milk diet, the daily administration of one to two grams of acetate of ammonium during the eruption, washing out the mouth with aromatic boiled water and injecting mentholized oil into the nasal cavities. Thirty-two cases were treated with 20 c.c. of Roux's serum, from suspicion of diphtheria in their angina with streptococcus albus. An eruption resembling measles followed two weeks later, confirming Sevestre's statement that this transient eruption is liable to follow the use of the serum in angina with streptococci.—*Gazette Médicale de Paris*, May 16.

Disinfection of Apartments.—There is apparently room for great improvement in the processes and agents for the disinfection of rooms after contagious diseases. In some recent experiments by the health department of one of the largest American cities, where it might be supposed disinfection had been reduced to a science, it was found that cultures of the potato bacillus, *B. mesenterica*, exposed in apartments undergoing sulphur dioxid fumigation, were growing vigorously when returned to the laboratory. Dr. Miguel has made a series of experiments on this subject, the reports of which are published in *L'Annales de Micrographie*, and from which it appears that the commonly used disinfectants, such as phenol, thymol, sulphurous acid and naphthalene, are either ineffectual or very expensive. Carbolic acid, for instance, is about as active as alcohol

or brandy, and less so than vinegar. The vapors of acetic acid are very active, but too expensive for ordinary use. Essential oils appear to be about as active as phenol. Concentrated aldehyde, in 1 to 2 per cent. solutions, should be used, exposed in shallow dishes and allowed to disengage their vapor slowly for several days. Another plan recommended is to burn methyl alcohol slowly in lamps surrounded with platinum gauze. Very penetrating vapors of aldehyde are disengaged, which do not alter metals or the colors of textile fabrics, while acting efficiently as a disinfectant.

To Prevent Adulteration of Food and Drugs in California.—A law was passed in California in 1895 that no person shall, within that State, manufacture for sale, offer for sale or sell any drug or article of food which is adulterated. The term "drug" is to include all medicines for internal or external use, antiseptics, disinfectants and cosmetics. The term "food," as used, is to include all articles used for food or drink by man, whether simple, mixed or compound. Any article shall be deemed to be adulterated, in the case of drugs: 1, if, when sold under or by a name recognized in the United States Pharmacopeia, it differs from the standard of strength, quality or purity laid down therein; 2, if, when sold under or by a name not recognized in the United States Pharmacopeia, but which is found in some other pharmacopeia or other standard work on materia medica, it differs materially from the standard of strength, quality or purity laid down in such work; 3, if its strength, quality or purity falls below the professed standard under which it is sold. Every person manufacturing, exposing or offering for sale, or delivering to a purchaser, any drug or article of food included in the provisions of this act, shall furnish to any person interested or demanding the same, who shall apply to him for the purpose, and shall tender him the value of the same, a sample sufficient for the analysis of any such drug or article of food which is in his possession. Whoever refuses to comply, upon demand, with this last requirement, or whoever violates any of the other provisions of this act, shall be fined not exceeding \$100, nor less than \$25, or imprisoned not exceeding 100 days nor less than 30 days, or both: and, in addition, any person found guilty of manufacturing, selling or offering for sale such adulterated food or drugs, shall be adjudged to pay all the necessary costs and expenses incurred in inspecting and analyzing such adulterated articles.

Poisoning by Plumbo-solvent Water-supplies.—A special report to the Local Government Board of Great Britain, made by Inspector W. H. Power, gives the results of an important original investigation concerning the effects of "moorland waters," in respect of their plumbo-solvent ability. The *Glasgow Sanitary Journal* for March gives an analysis of the report, holding it up as a brilliant example of modern scientific research, comprehensive, detailed, patient. The results, so far as the scrupulous accuracy of science will allow them to be stated, go on the whole to confirm the microbe theory of lead solution. The investigation is not yet ended; but the chief propositions are these: 1. The lead-dissolving property of moorland waters is associated with acidity. "Moorland waters that are acid invariably possess ability to dissolve lead. At the same time they may, or may not, erode this metal. Many moorland waters which dissolve lead to a considerable extent possess, in regard of this metal, no conspicuous erosive power. Other moorland waters both dissolve and erode lead in a very decided fashion. Moorland peat waters are all, it would seem, not far removed from possession of one or the other property, or of both properties." 2. "There was indication also of close relation between amount of acidity and vigor of solvent action on lead." But the correlation does not amount to complete parallelism. "Different waters of equal acidity did not necessarily possess equal power of dissolving lead." 3. In certain

circumstances moorland waters are found to increase in acidity, and therefore in lead-dissolving potency. This is true of waters on peat soil. 4. Peat soil, from various gathering grounds, was "found to be, when moist, invariably acid." 5. When divorced from the peat, the moorland waters did not increase in acidity. 6. When "sterile (neutral) peat-essence" was added to "freshly-collected samples of acid moorland water," the result was bacterial growth and, in most cases, acid reaction in the peat-essence. 7. When the acid water was added to the peat-essence (sterile and neutral), the result was bacterial growth and, in most cases, acid reaction in the peat-essence. 8. Thus the water must have contained bacteria that, by acting on some substance in the peat, were capable of increasing the acidity of the mixture. 9. These bacteria are derived from the peat. 10. "To separate samples of distilled water that was neutral in its reaction and which did not dissolve lead there were added small amounts in each instance of moist peat soil from different selected gathering grounds. As a result every sample of distilled water developed in a short while acid reaction and was found to have acquired ability to dissolve lead." 11. To separate samples of sterile peat decoction which did not dissolve lead there were added minute amounts in each instance of moist peat soil from different gathering grounds. As a result the samples of peat decoction always developed bacterial growth, and at the same time were usually found to possess acid reaction and ability to dissolve lead." 12. Of the microbes discovered in the above peat decoctions only two, named provisionally "O" and "Q," were found to make sterile peat decoction acid, and to confer on it the ability to dissolve lead. 13. Lastly, "moist peat soil from a variety of gathering grounds" yielded "two microbes identical with 'O' and 'Q' which, when inoculated into sterile peat decoction, multiplied therein with considerable vigor, produced in the medium acid reaction, and conferred on it ability to dissolve lead." These brilliant results will now be applied to the vast areas selected. The distribution of lead poisoning will be checked and verified. Doubtless many peculiarities, otherwise unexplained, will now fall into their place as natural deductions from the life history of these microbes. And thus, surely a sufficiently startling conclusion, lead poisoning by moorland waters almost leaps into the circle of infectious diseases!

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon-General, U. S. Marine-Hospital Service:

SMALLPOX (UNITED STATES).

Louisiana: New Orleans, May 23 to 30, 17 cases, 5 deaths.
Ohio: Dayton, May 28 to June 4, 1 case, 1 death.
Washington: Seattle, April 23, 1 case.

SMALLPOX (FOREIGN).

Alexandria, April 30 to May 6, 4 deaths.
Barcelona, April 1 to 31, 57 deaths.
Birmingham, May 16 to 23, 1 case.
Bristol, May 16 to 23, 1 death.
Buda Pesth, May 13 to 20, 3 cases.
Cairo, April 30 to May 6, 4 deaths.
Calcutta, April 18 to 25, 4 deaths.
Cardiff, May 16 to 23, 1 case.
Dublin, May 16 to 23, 1 death.
Gibraltar, May 10 to 24, 1 case.
Lecata, May 9 to 16, 2 deaths.
Madras, April 25 to May 1, 2 deaths.
Madrid, May 12 to 19, 18 deaths.
Montevideo, April 25 to May 2, 2 cases.
Naples, May 16 to 23, 3 cases, 1 death.
Odessa, May 9 to 16, 11 cases, 3 deaths.
Prague, May 9 to 16, 5 cases.
Riga, March 1 to 31, 1 death.
Rio de Janeiro, May 2 to 9, 1 death.
Singapore, March 1 to 31, 1 death.
Southampton, May 16 to 23, 1 case.
St. Petersburg, May 2 to 16, 46 cases, 7 deaths.
Swansea, May 9 to 16, 1 case, 1 death.
Tuxpan, May 9 to 16, 5 deaths.

CHOLERA.

Egypt: Alexandria, April 30 to May 6, 20 deaths.

India: Calcutta, April 18 to 25, 274 deaths; Singapore, March 1 to 31, 4 deaths.

YELLOW FEVER.

Cuba: Havana, May 21 to 28, 13 cases, 7 deaths; Santiago, May 16 to 23, 2 deaths; Sagua la Grande, May 16 to 23, yellow fever on increase among the troops but number of cases not given.

Brazil: Rio de Janeiro, May 2 to 9, 38 deaths.

Mexico: Vera Cruz, May 21 to 28, 5 cases.

SOCIETY NEWS.

Michigan State Medical Society.—The thirty-first annual meeting was held at Mt. Clemens, June 4 and 5. It disposed of eighty-four papers, though its sections held two business sessions and "broke bread together" at a banquet.

This simple statement makes it evident that no time or energy was left for useless or demoralizing contests. The Society began its work at eight o'clock, and pursued it continuously during the entire period of two days and one night, except from three till eight of the second morning which was yielded to sleep, and the time consumed in regular meals.

In brief the program was as follows: General session from eight till lunch; section work from lunch till dinner; session for annual addresses from dinner till nine; exhibition of X rays in their medical aspects from nine till ten; banquet from ten till three; sleep from three till breakfast; section work from breakfast till eleven; general session from eleven till lunch; closing section work from two till five.

The general sessions received and acted upon the reports of officers and committees, elected officers, discussed questions of general interest, and transacted all other business.

The Society received into membership a graduate of an eclectic medical college who had renounced his exclusive dogma and followed the practice of physicians. The Society last year took into its membership a graduate of a homeopathic medical college who had likewise renounced his exclusive dogma, and practiced as a physician. Thus the Michigan State Medical Society is on record as receiving into its fellowship physicians who have received all their medical college training at sectarian colleges. Hence, all graduates of homeopathic and eclectic medical colleges are eligible to membership in the Michigan State Medical Society, if only it is shown that they are legally qualified to practice medicine within the State, and are regarded by the physicians who know them best as being competent for their professional work, and honorable in their relations to the laity and the profession.

It is to be noted that this action of the Society was taken after a committee appointed for this purpose reported that its present constitution, by-laws and the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION, fully supported this view of membership qualifications.

DR. C. HENRI LEONARD, of Detroit, was chairman of that committee, and his extended report may interest such as have held other views respecting the qualifications for membership in regular medical societies. It is another practical indication of "drifting" of the medical profession away from tenets held in the past.

Another point of general interest, was the result of an effort to abolish the sections of the Society, and have all the scientific work done in general session. Not a vote was recorded in favor of such a retrograde movement. Having found a better way than the old "convention" medical society, the profession of Michigan unanimously refused to depart from it. The matter was fully discussed, both at this meeting and on former occasions. In fact the transformation of this Society under the pacific influences of sectional scientific meetings has been little less than marvelous. Its transactions have developed from a little pamphlet which few noticed, to a large and handsome volume which no student of scientific medicine can afford to pass unstudied. The members have their differences, as of

old; there are still cliques, politicians, pure and simple: there are "points of order" men, the vain glorious just as of old, but under the new system by which scientific work, rather than the arts of the medical politician and demagogue, bring honor and glory and profit, these are really being transformed and contribute much to the common profit. No longer is it possible to array one faction against another, and by hard words and harder deeds bring discomfort and distress to the non-participants.

The multiplication of sections multiplies officers, so that the office-holding ambition of the members has many times the opportunity for gratification. Then among the officers of the several sections there is a friendly rivalry in the securing of the best papers and discussions, and the accomplishment of the largest amount of section work. Members finding their papers discussed by the peers prepare them more thoroughly, so they can withstand the finest criticisms. No physician can attend these meetings and not feel adequately repaid in the accumulation of knowledge which will make him better able to do his work, and so earn more and better fees. All this is simple practical sense, and unquestionably increases the business of the members, and enhances the esteem in which the laity hold the profession.

A committee was appointed to consider the scheme of establishing a club house for the profession of Michigan in Detroit, of which matter more will be said later. The matter of a medical journal for the Society in lieu of its volume of transactions was presented for consideration.

The general addresses were especially happy in their selection of subjects, and treatment of the same. These addresses are designed to form a connecting link between the Society and the people of the town in which the meetings are held, in short, to be semi-popular. This year DR. H. M. KING, of Grand Rapids, discussed "Physical Diagnosis and Modern Therapeutics"; DR. VICTOR C. VAUGHAN "William Beaumont and his Work"; DR. C. H. BAKER, of Bay City, "The Doctor and his Hobby Horse"; DR. REUBEN PETERSON, of Grand Rapids, "The Prevention of Pelvic Disease." All of these were brief, to the point and very interesting.

Of the work in the several sections, it is enough to say that the papers were of varying degrees of scholarship and practical worth, but the average was quite equal to the Society's standard. The discussions were numerous and valuable. In some of the sections business would have been advantaged by the inflexible enforcement of a twenty minutes rule for papers, and five minutes for discussions.

DR. HUGH McCOLL, of Lapeer, was elected President; DR. C. T. SOUTHWORTH, of Monroe, Vice-President; DR. COLLINS H. JOHNSON, of Grand Rapids, Secretary; and DR. W. G. HENRY, of St. Clair, Treasurer.

The attendance of members was good, the accommodations excellent, so that nothing marred the entire session.

The next meeting will be held in Grand Rapids, May, 1897.

New Hampshire Medical Society.—This Society held its 105th anniversary meeting in the city of Concord June 1 and 2, the President, Dr. Eugene F. McQuesten, of Nashua, in the chair. The meeting was well attended, there being 105 members present. The usual routine business incident to the opening of society meetings was transacted, when the rest of the day was taken up in the reading and discussion of papers, which were of a high order and were received and discussed with animation and with much benefit to all present. The second day the society met at 8:30 A.M., when for an hour or more the time was consumed by the reading and adoption of reports of committees and election of officers. The membership of the society was increased by the admission of twenty-four physicians and surgeons. An essay on "Altitude: Its Effects upon Different Individuals, with Report of Two Cases," by Dr. George F. Gove, of Whitefield, was discussed by Drs. Conn and Hiland, of Concord. A report of how to manage an epidemic of "Variola" in small towns and cities was made by Dr. Cook, of Concord, and discussed by many members of the association, after which the President gave his annual address, which was a strong paper reviewing the progress of medicine, and introducing new features and work for the society in the future.

The following officers were elected: President, Dr. Abel P. Richardson, Walpole; Vice-President, Dr. M. C. Lathrop, Dover; Treasurer, Dr. M. H. Felt, Hillsborough Bridge; Sec-

retary, Dr. Granville P. Conn, Concord. The Executive Committee consists of Drs. Charles R. Walker, Concord; W. T. Smith, Hanover; George D. F. Towne, Manchester; F. E. Kittredge, Nashua; F. A. Stillings, Concord; A. C. Heflinger, Portsmouth; Ira J. Prouty, Keene. Necrologist, Dr. J. J. Berry, Portsmouth; Anniversary Chairman, Dr. James T. Greeley, Nashua. There was also elected a board of censors of ten members and a council consisting of twenty members. The exercises of the meeting closed with the anniversary dinner, at which about one hundred sat down to the table.

American Pediatric Society and the Odious Antivivisection Bill.

We, the undersigned members of the American Pediatric Society in session May 27, 1896, in Montreal, Canada, indorse the following memorial to the Congress of the United States, J. C. Wilson, Vice President, Philadelphia; Samuel S. Adams, Secretary, Washington, D. C.; Rowland G. Freeman, New York; Frederick A. Packard, Philadelphia; Wm. Osler, Baltimore; A. H. Wentworth, Boston; W. P. Northrup, New York; J. P. Crozer Griffith, Philadelphia; L. Emmett Holt, New York; Charles W. Townsend, Boston; J. Henry Fruit-night, New York; Geo. N. Acker, Washington, D. C.; C. G. Jennings, Detroit; Augustus Caillé, New York; A. C. Blackader, Montreal; J. Seibert, New York; Charles P. Putnam, Boston; Floyd M. Crandall, New York; T. M. Rotch, Boston; W. S. Christopher, Chicago; W. D. Booker, Baltimore; Dillon Brown, New York; John Dornig, New York:

WHEREAS, A bill is at present pending before the Congress of the United States entitled "An act to prevent cruelty to animals in the District of Columbia," which curtails experimentation upon animals, and would put a stop to medical research; and

WHEREAS, It is very probable that such legislation would influence greatly similar legislation in the various States which would prevent the advancement of medical science and of medical education; and

WHEREAS, Such legislation would be very prejudicial and is not called for by any existing facts of cruel experiment, as the advocates of the bill themselves concede so far as the District of Columbia is concerned; be it

Resolved, That the American Pediatric Society, now in session at Montreal, presents these resolutions as a memorial to Congress and enters a protest against the enactment of such legislation, declaring it to be needless and injurious; and be it further

Resolved, That a copy of these resolutions be sent to the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and to the other weekly journals. Carried.

SAMUEL S. ADAMS, M.D., Secretary.

The Wisconsin State Medical Society held its semi-centennial session in Madison, June 3-5, with about 150 physicians in attendance. The entire session was devoted to preventive measures and hygiene, the discussions including the sewerage and water supply, sanitation of public conveyances, elimination of contagious diseases, measures to prevent spread of diphtheria, hygiene of public schools, etc. Mayor A. A. Dye welcomed the visitors to the city, President Epley making response. The papers included: "The Rights of the Individual and of the Public in the Matter of Quarantine," by Dr. W. H. Washburn, Milwaukee; "Hygiene of Public Conveyances," by Dr. J. F. Pritchard, Manitowoc; "The Vital Statistics Problem in Wisconsin: a Remedy," by Dr. U. O. B. Wingate, Milwaukee, secretary of the State Board of Health. Officers elected for the ensuing year: President, B. O. Reynolds, Lake Geneva; vice-presidents, William Mackie, Milwaukee, and Margaret Caldwell, Waukesha; secretary, Charles S. Sheldon, Madison; treasurer, S. S. Hall, Ripon; censor, W. T. Sarles, Sparta.

American Association of Genito-urinary Surgeons. At the tenth annual session of this association, held at Atlantic City, N. J., June 1, the following officers were elected: President, Claudius H. Mastin, M.D., Mobile; vice-president, Francis S. Watson, M.D., Boston; secretary, W. K. Ottis, M.D., New York; members of council, L. Bolton Bangs, M.D., New York, and John A. Fordyce, M.D., New York; delegate to national convention, R. W. Taylor, M.D., New York; alternate, E. L. Keys,

New York. The next convention will be held in Washington, D. C.

Pan-American Medical Congress. Prof. Dr. Don Francisco Bastillos, Calle de Tacuba, No. 7, Ciudad de Mexico D. F. Republica Mexicana, has been elected Treasurer of the second Pan-American Medical Congress, to be held in the City of Mexico, beginning the 16th of November. All members residing in the United States and Canada, and others who contemplate attending, should forward the registration \$5, gold, to him at once and notify Dr. C. A. L. Reed, Cincinnati.

NECROLOGY.

WILLIAM LOCKHART, M.D., at his home near London, aged 80. He took his degree just sixty-three years ago and in 1838 volunteered for missionary work in China. He attempted to commence medical work in Macao, but in consequence of the hostility of the Portuguese he was compelled to desist and withdraw. He next visited Chusan, in the hope of being able to commence work there, but ultimately in 1843, he went to the newly opened port of Shanghai, where he labored with great success until 1857, when he returned to England on a visit. In 1861 he returned to China and commenced the first Protestant mission in Pekin, obtaining the privilege of settlement in the Imperial city in consequence of his official position as physician to the British Embassy, which was established there in that year. His volume, "A Medical Missionary in China," published in 1860, was full of interesting details of his work, especially during the war with that country, throughout which he heroically stuck to his post. Though his active work as a missionary ceased in 1864, he retained a vivid interest in missionary enterprise, and did all he could to help it on, acting as a director of the London Missionary Society and President of the Medical Missionary Society.

SIR J. RUSSELL REYNOLDS, President of the British Medical Association. The London papers state that Sir J. Russell Reynolds, Bart., M.D., the celebrated English physician, author and lecturer, Physician in Ordinary to Her Majesty's household, died May 22, aged 68 years. Sir J. Russell Reynolds was a grandson of Henry Revell Reynolds, M.D., who was Physician in Ordinary to George III. He was appointed Physician in Ordinary to Her Majesty's household in 1878, and was made a baronet in 1895. The following minute was made by Mr. Malcolm Morris, editor of the *Practitioner*, at the time the last named honor was bestowed by the Queen: "Sir Russell Reynolds as President of the Royal College of Physicians has been in every way a worthy successor of Clark and Jenner. As a physician he achieved the highest distinction almost without an effort. Success came to him without any of the weariness of hope deferred that makes so many a stout heart sick. Of Sir Russell Reynolds as a teacher it is enough to say that his light was not dimmed even by that of Sir William Jenner teaching in the same hospital. He had an extraordinary power of intellectual stimulation, and his lectures were so graceful in style and so rich in apt illustration that they held the attention of the idlest and aroused the interest of the dullest. It is not, perhaps, generally known in the profession that in addition to his medical writings Sir Russell Reynolds has made at least one excursion into the field of pure literature in the form of a novel written in conjunction with his brother, the Rev. Dr. Henry R. Reynolds, Principal of Cheshunt College, and published anonymously. I have not had an opportunity of reading the book; but Sir Russell's Introductory Address of thirty years ago, republished recently by the *Lancet*, shows that he has at least one of the qualities that go to the making of a successful novelist, viz., skill in characterization."

EDWARD JACOB FORSTER, M.D., Surgeon-General of Massachusetts, in New York, May 15, of cerebral hemorrhage. He was returning from Philadelphia, where he had attended the annual meeting of the Association of Military Surgeons of the United States, of which society he was Vice-President. At a meeting of the Boston Society for Medical Improvement held May 18, the following resolution were presented and unanimously adopted:

Resolved, That by the death of Dr. Edward Jacob Forster, the Boston Society for Medical Improvement has met with an irreparable loss. His prompt, fearless and incisive energy; his quick and ready intelligence; the thoroughness with which he performed many self-imposed labors for the good of his professional brothers, are recognized by all of us, and will never be forgotten.

Dr. Forster was born in Charlestown, of early colonial stock, on July 9, 1846. He received his degree in medicine from Harvard University in 1868, and then continued his studies in Paris and Dublin before establishing himself in practice in his native city. As his professional life unfolded, and wider interest of official and civil character enlarged his opportunities for usefulness, he ceased to be a local practitioner merely, and became identified with the larger affairs of Boston and the Commonwealth. Four years ago he removed his home to Boston. The Boston Medical Library is indebted to Dr. Forster for many years of faithful service as treasurer. The future of the library, and the plans for a new building engaged much of his thoughtful attention. The Obstetrical Society of Boston will long cherish the remembrance of his generous nature and of his service in various offices. Under his will his valuable medical library will be donated to the Boston Medical Library.

W. C. PEPINO, M.D., at Des Moines, Iowa, June 3. His death was the result of fracture of the skull by the kick of a horse from which he was thrown while riding. Dr. Pepino was a graduate of the University of Maryland School of Medicine, Baltimore, Md., 1873. He was Professor of Rhinology and Laryngology, Iowa College of Physicians and Surgeons; Member AMERICAN MEDICAL ASSOCIATION, Iowa State Medical Society, etc.

JOHN J. BRINKERHOFF, M.D. (Bellevue Hospital Medical College, New York, 1867), of Auburn, N.Y., of apoplexy, May 27. He was a veteran of the civil war.—Wilbur C. Curry, M.D. (University of Maryland School of Medicine, Baltimore), Baltimore, Md., May 28.

PIETRO GAMBERINI, M.D., died at Bologna. He was the oldest and one of the most esteemed dermatologists in Italy. He founded the *Giornale Italiano delle malattie veneree e della pelle*, among the first medical magazines devoted to a special branch.

GEORGE TRAILL, M.D. The Policlinique at Lille, France, and its publication are mourning the loss of their young founder, Prof. Traill. His numerous articles on his specialty, diseases of the uro-genital organs, were based on personal observation and experience, and have been widely copied.

MISCELLANY.

Presumption of Accidental Death.—Where the evidence as to a death being accidental or suicidal is so nearly balanced as to leave the question in doubt, the supreme court of Kansas holds, *Mutual Insurance Co. v. Wiswell*, May 9, 1896, the presumption is in favor of the theory of accidental death.

Payment not Prerequisite of Proof.—Proof of expenses incurred by a person injured for necessary medicine, medical attendance, and nursing, the supreme court of Utah holds, *Wilson v. Southern Pacific Co.*, April 15, 1896, may be made when properly alleged in the complaint, though they have not been actually paid.

Bellevue Hospital Medical College.—The following are among the recent changes in the faculty of that College: William P. Northrup was elected to the chair of pediatrics, and George D. Stewart to that of anatomy (adjunct). J. Lewis Smith, in consideration of his long connection with the college, was appointed Emeritus Professor of Diseases of Children.

Tetanus Cured with Calmette's Anti-tetanus Serum.—The *Bulletin Médical* of May 3, describes the case of a lad of 13, who cut his knee while wading in a filthy ditch, and developed a typical and distressing case of tetanus. Treated with chloral, morphin and three injections of 10 c.c. of serum in the course of three days, the lad had entirely recovered in a week.

Emotional Insanity.—The supreme court of New Jersey holds, *Genz v. State*, May 2, 1896, that it was not error for a trial judge to instruct the jury that emotional insanity is an insanity which depends upon the mere emotions of the time, arising from some defective or perverted moral sense, which begins on the eve of a criminal act and ends when it is finished.

Can Not Grant Temporary Certificates.—The attorney-general of Ohio, having been asked his opinion as to the right of the State Board of Dental Examiners to grant a temporary certificate of admission to practice, to students in dental colleges who have not finished their course, holds that the board can not do this, but must either refuse the certificate or else grant one admitting the applicant to full practice.

Polluted Jordan River Water Causes Death.—A recent cablegram from Berlin brings to light the fact that the illness which caused the death of Archduke Karl Ludwig, brother of Emperor Francis Joseph, who died in Vienna a few days ago, was ascribed by his physician to his drinking of the waters of the River Jordan, which he did as a matter of religious devotion upon the occasion of his recent pilgrimage to Palestine. The water of the Jordan is by no means pure, and in the case of the Archduke it had a tendency to bring on intestinal weakness, which could not be overcome.

Minnesota Inebriate Law Unconstitutional.—Chapter 156 of the General Laws of Minnesota of 1895, which is entitled "An act to provide for the treatment of inebriates by counties," etc., the supreme court of Minnesota holds invalid, for the reason that it assigns to the probate judge powers and duties beyond the jurisdiction authorized by the constitution. *Foreman v. Board of Commissioners of Hennepin County*, May 11, 1896. The proceedings authorized by the act, the court further says, do not amount to a commitment of an inebriate to the guardianship of anyone, and hence do not come within the general jurisdiction of "persons under guardianship" conferred by the constitution on the probate court, although the framer of the bill evidently intended to give it the appearance of a proceeding for the appointment of a guardian for the inebriate.

Serum Treatment of Diphtheria in Three Cities.—In the statistics of the Belvidere Hospital, Glasgow, for 1895 we note that while the annual mortality in cases of diphtheria during the previous five years averaged 38.3, in 1895, with the use of serum reached 14 per cent. Dr. Henry W. Berg, one of the attending physicians at the Willard Parker Hospital for Contagious Diseases, New York, reports that since the introduction of the antitoxin treatment of diphtheria in that institution not only had the proportion of deaths from the disease been greatly diminished, but the number of cases of post-diphtheritic paralysis in those who recovered had been far fewer than formerly. The St. Louis Board of Health has made public the conclusion of an official inquiry into the results of the treatment of diphtheria with antitoxin. The report covers 326 cases, of which 15 were fatal.

Gastropathy of Syphilitics.—Gastou and Babon have been studying this complication of syphilis, due to the medicine, or

to some predisposing alcoholism or chlorotic dyspepsia, or to some uterine affection or a floating kidney. They state that the chemie formula is hypopepsia, with retarded secretion of gastric juice, and abnormal fermentations. It commences either abruptly with burning sensations, pains and acid regurgitations, or proceeds more slowly with irresistible drowsiness, followed by pains and gases, but no vomiting. It often follows abuse of KI pills, and Hayem has found that Gibert's syrup is apt to produce it. With this tendency patients should avoid medication by the stomach, and be treated with mercurial injections and iodine externally. — *Annales de Derm. et de Syph.* April.

A Recruit for Achilles Rose.—A new style of prescription writing is recommended by Dr. Loeffler in the *Aerzt. Korrespondenzblatt*. The author calls attention to the fact that in prescribing the newer remedies, the names of most of which are familiar to the general public, the customary writing of prescriptions in the Latin language does not protect the physician from inconvenient criticisms of laymen, so that it often would seem advisable to adopt a style less intelligible to most persons. To this end Dr. Loeffler has used for some time the Greek alphabet though still retaining the Latin nomenclature, and in all the apothecary shops of Dresden his prescriptions are readily understood. E. g., he prescribes antipyrin as follows:

R ἀντιπυρίν 1.0
 Δ. ταν. Δωσ. Νω. Χ.
 Σ. Daily, etc.

Civil Rights.—The civil rights law of Illinois provides "that all persons within the jurisdiction of said State shall be entitled to the full and equal enjoyment of the accommodations, advantages, facilities, and privileges of inns, restaurants, eating houses, barber shops, public conveyances on land or water, theaters and all other places of accommodation and amusement, subject only to the conditions and limitations established by law, and applicable alike to all citizens." May 12, 1896, the supreme court of the State decided, in the case of Cecil v. Green, which was brought by a colored man because a drug-gist refused to sell soda water to him, that a drug store in which a soda fountain is kept, from which is dispensed the character of liquids usually sold therefrom, can not be considered a place of accommodation or amusement to any greater extent than a place where dry goods or clothing, boots and shoes, hats and caps, or groceries are dispensed, and is not within the purview of the statute. Nothing in this provision, the court says, requires a physician to attend a patient, a lawyer to accept a retainer, a merchant to sell goods, a farmer to employ labor, unless of his own volition, regardless of any reason, whether expressed or not.

The Cleveland College of Physicians and Surgeons. The school formerly known as the Medical Department of the University of Wooster, located at Cleveland, has become the Medical Department of the Ohio Wesleyan University, and will hereafter be known as the Cleveland College of Physicians and Surgeons. All steps in the transfer have now been completed. A very desirable lot, 80 by 120 feet in size, has been donated to the trustees of the University, upon which a building for medical college laboratory purposes is to be erected at a cost of not less than \$50,000. The funds for the erection of the building have already been pledged, and the structure will be ready for teaching purposes in 1897. This laboratory building together with the new Cleveland General Hospital which is entirely under the control of the college for clinical teaching purposes, will place the school in an excellent educational position. At the annual faculty meeting Dr. Charles B. Parker was elected dean of the new school, and Dr. H. W. Rogers re-elected secretary. The union of the medical school with the university is an intimate one, and it will doubtless prove advantageous to both institutions.

Iodized Vasogen in the Treatment of Syphilis.—Leistikow describes his experience with iodized vasogen, containing 6 per cent. of iodine, in the *Annales de Derm. et de Syph.* for April. In one case of recent secondary syphilis a course of frictioning caused the morbid symptoms to disappear, but they were followed by violent cephalgia, resisting every remedy, even iodine taken internally. Daily frictions of the scalp with five grams of iodized vasogen were accompanied by marked improvement in three days and a complete cure in three weeks. A case of extensive periostitis which had been only slightly improved by frictioning and the application of phenic mercurial plaster and iodine taken internally, yielded at once to a few massages a day with iodized vasogen, with a complete cure in fourteen days. Similar success was attained in a case of sciatic neuralgia, also in six cases of ano-genital patches, and a case of syphilitic pigmentation of the neck. In some of these cases all other treatment had been ineffectual; but in three cases of lupus vulgaris the results were absolutely negative. In one case of gummy tumors the cicatrization took place more rapidly than with any other treatment. Leistikow ascribes the superiority of iodized vasogen over the usual remedies for syphilis to the fact that the absorption of iodine with it is very rapid.

Indications for Irrigation of the Stomach.—Martius states as follows the indications for lavage of the stomach: 1. Acute poisoning: the introduction of the water dilutes the poison and renders it less harmful and it can be withdrawn with the fluid. 2. Stagnation in the stomach from stenosis of the pylorus, whether due to a benign or malignant growth. 3. All cases of occlusion of the intestines from whatever cause. Irrigation always relieves and may possibly cure without further treatment. Guerin commends it in the current *Archives de Bordeaux* for its action in arresting the painful vomiting of fecal liquids, while it allows medicines to produce their proper effect. It is also generally indicated in carcinoma ventriculi, acute and chronic catarrh and all functional diseases of the stomach. Also in tympanites such as occurs in severe abdominal typhus and in nervous dyspepsia and spasm of the esophagus. Others have found it very beneficial in infantile gastric and bowel troubles, acute and chronic. Some consider it ineffective in neurasthenia gastrica, but it often produces a cure in nervous dyspepsia when the patient can be made to see for herself that her stomach is digesting normally. Minkowski has found it very valuable in arresting hemorrhages. He suggests that the time of using it is very important; if the patient is allowed to eat again soon, the benefits are often lost. He advises it the last thing at night. Quincke uses the irrigator for removing the liquid also. — *Memorabilien* for April.

The Yuma Indians of New Mexico.—The Bureau of American Ethnology of the Smithsonian Institute has, according to the *New York Sun*, in preparation a preliminary report regarding this interesting tribe of aborigines. The treatment of the sick is one branch of the subject touched upon in that report, which shows that there is about the same grade of intelligence in this tribe and in its medicine-man that is exhibited by other and less interesting natives. The report, in part, says that the sick, no matter how exhausted or in what agony, are compelled to submit to the roughest handling from the medicine-man, who excitedly rolls his patient to and fro in frantic endeavors to discover the point of disease. The relatives, sitting upon their heels around the hut, are ordered to maintain silence, as noise would break the spell. Severe pain is attributed to sticks, as, for example, when the physician supposes that the heart is affected, he loudly ascribes it as two sticks pushing upward from the stomach to the heart. Sucking with the lips upon the stomach is resorted to in order to soften the hard stick-like substance, for only when this is accomplished will the patient recover. Rapid touches upon

the breast draw out the pain in case of pneumonia, and deafness by blowing in the ear. Touching, slapping, expectorating, blowing and massage, associated at times with monotonous chanting, unearthly howling, and an occasional swaying dance, complete the usual course of treatment. Recovery under such circumstances is very doubtful. The debt in the event of recovery is liquidated with blankets, horses, money and other possessions, but nothing is forthcoming should the patient die.

Innervation of the Intestines.—Pal states that not only the stomach, the small intestine and the upper third of the colon, are innervated by the vagus, as hitherto accepted, but also the whole of the colon and rectum. He experimented on curarized dogs, endeavoring to determine whether there were any controlling motor centers for the intestines below the splanchnic centers in the spinal cord. Simple section of the dorsal portion of the spinal cord (from the sixth to the tenth dorsal vertebrae), causes more violent movements when stimulus is applied to the vagus. If the lower dorsal or lumbar vertebrae are removed, the intestines assume a different appearance. (Animals from $\frac{1}{2}$ to $1\frac{1}{2}$ years are best for these experiments.) The vessels become fuller, the intestinal walls thicker and the intestine itself begins to move with a peculiar motion resembling the pendulum swing of a rabbit's intestines. Stimulus applied then to the vagus produces a much stronger action than before, with a noticeable shortening of the time between the stimulation and the response. If, however, the lower part of the spinal cord is removed and the nervi splanchnici severed, the intestines also assume the above conditions. When then the vagus is irritated, violent peristaltis ensues, but this movement is controlled by applying stimulus to the stump of the splanchnicus, which proves the existence of other centers in the spinal cord below the splanchnicus, controlling the peristaltic action of the intestines.—*Centralblatt f. Physiologie*, April 4.

Explorations of an American Physician.—Dr. Donaldson Smith, of Philadelphia, recently addressed the Drexel Institute regarding his adventures in Somaliland, parts of which had never been seen by a white man. He had been gone from his home less than two years. In July, 1895, after many hardships and privations, the explorer reached the eastern shore of Lake Rudolf, near the northern end, and he had passed through a country that no white man had ever set foot in before. On July 19, leaving the caravan at the lake, Dr. Smith turned north to explore the Nianann river, which empties into Lake Rudolf. He was taken with fever and turned back, but set out a few weeks later and explored the country one hundred miles north. On his return to the lake the party journeyed to the southern end, incidentally discovering that the River Bass, which a former explorer is said to have discovered emptying into Lake Rudolf, does not exist. A peculiar source of discomfort to the party was the frequent invasion of rhinoceroses, these animals taking particular umbrage at an exploration of their native haunts, and venting their spite by driving the human beings into the thorn bushes for refuge. Four carriers were injured and two camels killed by these beasts. One of the carriers had an arm bitten off by a crocodile, and Dr. Smith amputated the rest of the injured member. The explorer discovered a mammoth cave formed on the River Webi by the erosion of the rocks. The roof was supported by great pillars, shaped like double cones, and so regularly arranged that they seemed to have been carved by the hand of man. He also visited a small town beyond the borders of Somaliland, built by the Arabs many years ago, though geographers say that the Arabs never penetrated so far. It was built and ruled originally by Sheikh Huslin, a Mahomedan saint, who came there two hundred years ago. It was here that some of his followers became discontented and an outbreak occurred, which, however, was soon quelled.

The Champion Quack of Modern Times.—The *London Lancet*

announces the death of Count Mattei, of Florence, speaking of him as "the most successful irregular practitioner of the nineteenth century. He was a fat spider who sat at the center of a web whose ramifications extended all the world over and enmeshed patients of high and low degree, especially the former." Statesmen and diplomats, men to whose judgment and *finesse* the most momentous as well as the most delicate missions were confided, had no hesitation in entrusting their health, mental and bodily, to a man who studied medicine by himself—note the order—after having discovered his great secret. And they were quite ready to show cause for the faith that was in them and one and all to assure their hearers that, having found orthodox medicine useless or worse, they had got rid of their ailment (whatever it was), and regained their powers of work and enjoyment of life by Count Mattei's "granellini di zucchero saturi di elettricità bianca, bleu, rossa o verde" (sugar granules charged with white, blue, red or green electricity), which were equally good for tuberculosis or chilblains, anemia or plethora, cancer or wry-neck, acute melancholia or inhibitory paresis. Under the shelter of social prestige and aristocratic testimony, Count Mattei added daily to his "miraculous cures," and steadily amassed a fortune which, in the language of a panegyrist, "made him several times over a millionaire." Vainly did foreign custom houses interpose their barrier to the import of his "granellini." Vainly was the law invoked against the sale of patent medicines, the composition of which was undeclared even to the licensing authority. "Agents" were found not only to introduce the granules into every Christian country, but to effect their sales in quarters the most conspicuous and exposed, and the army of such functionaries, subsidized by Count Mattei at considerable cost, still left the gains from the "business" enormous. Dying the other day at Bologna, he has bequeathed two million lire (\$400,000) to charities, while the bulk of his fortune descends to his adopted son and heir, Mario Venturoli Mattei, to whom he has also left his "segreto miracoloso."

The Tsetse Fly Disease of South Africa.—It has been said of that terrible horse and ox destroyer, the tsetse fly, that it is "an ill wind that blows nobody any good;" and that this ravaging insect has been a very considerable drawback to the land-piracy and territorial greed of the European, in that part of the world. But now science bids fair to come to the relief of land thieves of Europe, by discoveries that have been made regarding the true cause of the elective fatal operations of the fly. In the *British Medical Journal*, for May 16, it is made known that Surgeon Captain David Bruce has discovered that the true cause of the tsetse fly disease is not any secretion or property of the fly itself, but that the fly is merely the passive agent for conveying a living virus from infected to uninfected animals. This virus he has clearly shown to be a protozoon, closely resembling, if not identical with, the trypanosome evansi, the acknowledged cause of the surra disease of India, and possibly, identical with the similar flagellated organism found in the blood of rats and hamsters in England and on the continent of Europe. Bruce has also shown that when the tsetse fly, after feeding on the blood of an affected animal, proceeds to feed upon an unaffected animal, it introduces the trypanosome with its bite; and that after a short incubation period the trypanosome appears in the blood of the latter concurrently with the outbreak of fever, and that sooner or later death is almost inevitable, a high degree of anemia, accompanied by wasting and dropsical swelling, preceding the fatal issue. Surgeon Captain Bruce's discovery will draw attention once more to the part played by insects, particularly bloodsuckers, as factors in pathology. The role of the mosquito is beginning to be recognized; that of the tsetse is now established and possibly, ere long, other bloodsuckers will be found to possess similar properties, either as active agents in the biologic cycle of disease germs,

as in the case of the mosquito, or as media for their conveyance from one human being or from one animal to another, as the case of the tsetse fly. Diseases with peculiarly localized geographic distributions—distributions apparently not directly dependent on climate, but on some strictly local and limited circumstance—may be conveyed in the same way as this tsetse fly disease, and owe their peculiar geographic distribution to something of the same sort. The name by which the tsetse fly is known to entomologists is "glossina morsitans;" it is a dipterous insect, somewhat larger than the common house-fly.

The Medico-Legal Value of Ecchymoses Questioned.—The *Medical Press and Circular* is led to caution the profession against a too ready acceptance of the *prima facie* evidence of ecchymoses. The editor of that journal treats the subject in a leading article, in the feeling of a witness who "had been there." He writes, in part, as follows:

"It is now a well-recognized fact that more or less considerable extravasations of blood may take place beneath the skin or of the mucosæ or on to the surface of the internal viscera from purely physiologic causes, giving rise, however, to appearances which might easily be mistaken for the results of violence in some form or another. The possibly natural origin of such ecchymoses seems only to have been recognized within the last decade or two, and this fact suggests some uncomfortable thoughts concerning probable injustice to accused persons in the past. When a certain French medico-legal authority first called attention to petechial ecchymosis on the surfaces of the lungs it was for the purpose of promulgating the view that they afforded evidence of death from suffocation in one or other of its forms. This has since been proved not to be the case, for they have been met with in connection with action of particular poisons, particularly those belonging to the benzine series, as well as after death from burns, etc. Although these extravasations thus lose the diagnostic value which had been attributed to them, the subject is one well worthy of attention in order that full light may be thrown upon the mechanism of their production. For instance, they are not unlikely to occur in the insane, and in this event their presence on the skin would not unnaturally give rise to unfounded suspicions of violence at the hands of the attendants. In a paper dealing with this subject at a recent meeting of the Royal Medical and Chirurgical Society, Dr. Lediard laid particular stress upon the possibility of such ecchymoses on the mucous membrane of the vulva and vagina leading to the presumption of rape. Their position in the body, their delicacy of structure, and their vascularity render this portion of the female anatomy peculiarly liable to exhibit punctiform ecchymoses in virtue of the same causes that determine their appearance elsewhere. Mr. Hutchinson quoted a striking instance of the production of extensive ecchymoses in an elderly gentleman as the result of an attack of whooping cough contracted from his grandchild. As any medical man is liable to be called upon to discharge the delicate and responsible function of medical assessor in criminal cases, it is highly desirable that a knowledge of this curious phenomenon should be widely disseminated, for it is not difficult to imagine various circumstances in which these ecchymoses would probably be ascribed to violence or asphyxia, instead of to their real cause whatever that might be in the particular case."

Compensation in Case of Malpractice. The supreme court of Iowa affirmed, in the case of *Whitesell v. Hill*, April 11, 1896, a judgment for one dollar against a physician who was charged with malpractice in reducing a fracture of the plaintiff's arm. While it might be that the verdict of the jury was the result of a compromise, yet the court thinks it was not so discordant as to justify it in interfering in behalf of the plaintiff, who took the appeal. It says that the jury might well have found that the condition of the plaintiff's arm, as it appeared at the time of the trial, was in a large measure contributed to by an injury he received after the defendant had ceased his treatment. The court holds that a physician is only required to exercise the average degree of skill, learning, and ability possessed by members of the medical profession in the locality where he practices, the word "average," as used meaning the same as "reasonable" and "ordinary." It also holds that it was proper for the trial judge to instruct the jury to consider the condition of the plaintiff's arm as it appeared upon the trial, but

that they were not justified, from this alone, in finding for him that they must also find such result was due to defendant's negligence in the treatment of the injury. And it holds that the trial judge properly told the jury that the burden was upon the plaintiff to show his freedom from negligence contributing to the injury. Then, it was argued that the two claims, for service and for malpractice, could not coexist, and that a recovery by either was a bar to an action by the other. Admitting that there are some authorities in support of this contention, the court says that it does not think these cases announce the correct doctrine. The rule in Iowa, long ago established, is that a party who has failed to perform his contract in full may recover compensation for the part performed, less the damages caused by his failure to perform the whole contract. It does not necessarily follow, continues the court, that, because a physician or surgeon may be guilty of negligence, which causes some inconsequential or inconsiderable injury, he is to be deprived of all compensation for his services on account thereof. Whether he shall lose the value of his services depends upon the amount of damages suffered by reason of his neglect to perform his duty. No penalty beyond the amount of the actual damages sustained is to be visited upon him because of his negligence or want of skill.

Inhalations of Iodin and Carbon Disulphid in Phthisis.—Drs. Stovall and Twitty, of Columbia, Ala., write to the *New York Medical Journal* regarding the use by inhalation of the above named and other substances, in pulmonary tuberculosis. They have found the disulphid to be volatile at ordinary temperatures and an ideal vehicle for carrying iodine to all parts of the laryngeal and lung areas.

"We are quite positive that by deep inspiration the remotest recesses and apical caseations are reached. The good effects are manifest during the first day's trial, and the night cough which is so troublesome and exhausting is much improved, and this is among the first benefits derived. Expectoration is lessened in quantity and the quality is made decidedly better in a short time. The sulpho-carbon compound is put down as poisonous, and we have watched very closely for any untoward symptoms attributable to its inhalation, but so far have failed to note any objection to its use under proper precautions and directions from the physician. About a 12 per cent. solution, or, more accurately, one of a drachm of iodine to the ounce of disulphid, is what we have used in practice. Owing to the solubility of rubber and kindred matter in the disulphide, it is rendered inadmissible as material for an inhaler, which should be made of glass preferably.

"A cheap, convenient instrument may be improvised by using a small test tube with a sponge in the bottom saturated with the liquid: it will be necessary to replace the sponge frequently, because of the corrosive action of the medicine. For lung and laryngeal treatment, the inhalation is to be made through the mouth with the instrument pushed far back, approximating the opening of the larynx. The frequency with which it may be used is variable according to the individual condition and effects; we may say, on an average, once every two hours during the day. The bisulphid has a bad odor which is objectionable to some patients. We have experimented with a view to rendering it more agreeable and have made various additions and modifications, resulting with no advantage considerable enough to justify the use of anything additional, inasmuch as such a change might possibly lessen the practical value of the original formula. Menthol is perhaps the most harmless addition that we have attempted. We should be very glad if the profession would prove the efficacy of the treatment and report the results."

Gastrostomy. The following is an account of a successful gastrostomy in the practice of Mr. William Battle, of St. Thomas Hospital, as reported in the *Medical Press and Circular*. The patient was a male, aged 60 years, with a malignant stricture of the lower part of the esophagus from which he had been suffering for some six months. He was unable to swallow solid food of any kind, but could still swallow fluids: he did not suffer any pain, but was emaciating rapidly and losing strength. No bougie could be passed through the stricture. One had been passed on a former

visit about a fortnight before. There was no sign of disease elsewhere, and the patient agreed to submit to operation after the nature of it had been explained to him. It was decided to perform the operation in two stages, and by a method which permitted of quick operation. The oblique incision was made in the usual situation parallel to the left lower ribs and deepened down to the rectus muscle, the fibers of which were separated, and the remainder of the incision continued in the longitudinal direction. The abdominal wall was unusually thick for a case of gastrostomy, as there had been comparatively little loss of the subcutaneous tissue. The stomach was easily found and drawn into the wound. The portion selected for the opening was carried to the extreme right of the oblique incision and then two stitches passed through the peritoneum and walls of the stomach, one above and the other below, so as to shut off the peritoneal cavity. The highest point selected for the opening was drawn through a Senn's bone plate and transfixed with two hare-lip pins, which did not, however, enter the interior of the stomach. A trocar and canula were then passed between the pins into the stomach, and on withdrawal of the trocar a No. 1 catheter was introduced through the canula into the stomach, and the canula withdrawn over it. A stitch was then passed through part of the stomach wall, and the ends tied around the catheter. The external wound was closed with interrupted sutures, the bone plate being left across the upper part and at right angles to it. Cyanid gauze was applied to the wound, a many-tailed bandage put on. The end of the catheter was plugged and brought into the cotton wool of the dressing. Two points, Mr. Battle said, were of importance in performing the operation: first of all, by going between the fibers of the rectus muscle, he hoped to obtain a kind of sphincter action: secondly, by carrying the opening as high up as possible, he hoped that further obstacles to the escape of gastric contents would be prevented as the mouth into the stomach would be considerably higher than was usually the case after gastrostomy. The patient's great complaint after this operation is of the irritation caused by the escape of the gastric juice, which produces troublesome eczema and much soreness for some distance round the opening.

The New Japanese Dressing for Wounds, Straw Charcoal.—The physician attached to the French Embassy at Pekin, "Aide Major de l'armée" and physician to the Russian Embassy writes to the *March Archives de Bordeaux*, describing the superior advantages of this new dressing, suggested by Kikuzi in 1891, and used with great success after the earthquakes and during the last campaign. He writes from personal observation on the field and in the hospitals in Japan, where it is exclusively used, and states that the results obtained with it after the battles of Port Arthur and Wei Hai Wei were admirable, while among the Chinese wounded tended by English medical missionaries, the results of treatment were deplorable. The Japanese use rice straw, but any straw is equally as good, and the process of preparation disinfests it thoroughly. It forms a brownish, almost black, powder, composed of the charcoal, fragments of unconsumed straw, dust and ashes. The analysis shows the following ingredients in a hundred parts: Silicate of soda, 54.207; chlorid of sodium, 11.185; carbonate of potassium, 8.679; phosphate of soda, 7.673; carbonate of soda, 7.421; sulphate of potassium, 1.132; sulphate of soda, 1.132; magnesium, aluminum, organic matters, 8.561. The charcoal powder is exceedingly fine, porous and elastic, fitting smoothly and evenly over the wound, especially if applied in a soft bag as the Japanese use it. They employ fine linen for the bags, left open at one end, and used again and again, after washing and disinfecting. Like all charcoal it requires slow combustion without air. Small quantities are prepared as required by filling a boiler with straw and after

lighting it replacing the cover. Large amounts are charred in a closed room or kiln. The charcoal is then spread out to cool and the ashes sifted out as much as possible. To measure its absorbent power, Kikuzi dipped equal volumes of cotton, gauze and charcoal into water and then weighed them. Other similar portions he dipped into water and then placed them on a sloping board, under heavy equal weights, to determine which retained its moisture longest. He also experimented to determine the amount of evaporation in six tests. The following table shows the results of these experiments: Cotton 5 grams, maximum absorption 80, remaining after pressure 43, evaporation 4, 8, 13, 19, 26, 33; gauze 8 grams, maximum absorption 66, remaining after pressure 44, evaporation 4, 10, 17, 25, 33, 44; charcoal 15 grams, maximum absorption 65, remaining after pressure 58, evaporation 5, 10, 16, 24, 30, 43. The bags are kept on hand in three sizes, 10, 13 or 20 centimeters long by 7, 10 and 13 centimeters wide, with a uniform thickness of 2 centimeters. A freshly filled pad is best, but they can be filled and kept for weeks in a metal box. The cheapness of this dressing and its abundance everywhere recommend it especially for military use, as numbers of the bags can be always kept on hand ready for use, much less bulky and expensive than the gauze required in a campaign. To sum up its advantages: 1. its absorbent power is greater than gauze; 2, it is to be procured everywhere at a trifling expense; 3, it can be used without further disinfection, and its elasticity is equal to that of gauze. Simple, practical, quickly prepared and inexpensive, Dr. Matignon considers that it seems to realize all the conditions of an ideal dressing.

A Forgotten Medical Pathfinder.—Sir Richard Quain has lately addressed one of the London Medical Societies on the subject of Asiatic cholera. In the course of his address he expressed great regret that the profession had hitherto erected no memorial to the late Dr. John Snow, of London, the discoverer of the theory that cholera is a water-borne disease. It was in 1854, or forty-two years ago that Dr. Snow announced his views, "the result of a rigid scientific investigation which has done much toward the clearing up of the mystery of disease causation, and which has rendered an immense service to mankind that has not been recognized so fully as it should be." This is the language of Dr. Quain in his Dictionary of Medicine, and expresses the feeling which he has emphasized in the address referred to. As Sir Richard Quain is the President of the General Medical Council of Great Britain, we may confidently expect that his neglected hero will be properly honored. Dr. Snow was born in 1813 and died in 1858, having been at the time of his decease not more than twenty-five years in the profession; and he survived his epoch-making publication on the propagation of cholera only four years. The following is a portion of Sir Richard Quain's remarks upon the meritorious work of Dr. Snow, as reported in the *British Medical Journal*.

"Why is it that we are protected, and that cholera is prevented from invading us? It is very much owing to the researches of a man, probably hardly known to any of you—Dr. Snow. He is was who pointed out that cholera was propagated by polluted water. This conclusion was the result of close research, Snow's investigation being opposed by such eminent men as Dr. Baly and Dr. Gull. They did not believe that cholera was thus propagated. At last there occurred a very bad attack in the neighborhood of Golden Square, and the Broad Street pump became historical. Snow found that the people who drank water from that pump suffered from cholera, but those who did not, and took other water, escaped. An old lady and her niece migrated to Hampstead from this district, and died of cholera. There was not a case of cholera at Hampstead, but Snow showed that these good people had the water sent to them daily from their favorite pump at Hampstead. Nothing could be more confirmatory of the fact that cholera was propagated by poisoned water. These researches were extended by Sir John Simon and his able lieutenants, Drs. Parkes and Netten Radcliffe. Yet to-day possibly nine-tenths of the people now living do not know of Dr. Snow. There is no memorial; no monument. His name is unknown: but I hope, before I

leave this earth, I shall secure something in the shape of a memorial to him. Probably the best of all would be, on the Thames Embankment, a granite fountain with the inscription that Dr. Snow had saved millions of lives. He was a graduate of the University of London, a member of the College of Physicians, and lived in Savile Row. He died at 45 years of age. He was a most unobtrusive man, and is best known as having written on chloroform and anesthetics. We found memorials to all classes of people, and he is forgotten. He has been instrumental in saving the lives of millions. Had he been a successful general, responsible for the death of thousands, he would have received a peerage and a pension."

In commenting on these observations of Sir Richard Quain, the *Hospital* charges that the neglect of Dr. Snow's memory is the fault of the medical profession rather than of the general public, by saying that Dr. Quain sums up his indictment against his fellow countrymen in this sentence:

"Dr. Snow made us masters of the deadly plague of cholera." Dr. Snow thereby saved millions of lives. The sole reward which England has conferred upon Dr. Snow is midnight oblivion. If Snow had been a soldier the nation would have honored his memory with monuments more enduring than brass. No doubt that is so: and yet we can not blame the nation. The soldier is a very indispensable person, and though he slays rather than saves, he slays that his country may be saved, not only in its life, but in its freedom and its greatness. If we were to probe the facts to the bottom we should probably find that professional jealousy had much to do with obscuring Dr. Snow's great work. The unscientific community could not take the true measure of his researches and conclusions. We have seen how Gull and Baly opposed. If they were skeptical, how could the majority of the profession believe? Above all, if medicine as a whole withheld its faith, how could the unscientific public be more appreciative than its medical guides? Medicine has often before made the *amende honorable*, especially after the prophet's death. It is better that we shall honor a great name now, at any rate for the sake of our own honor and mental peace, than that we should not do it at all. "Before I leave this earth," said Sir Richard Quain, "I hope I shall secure something in the shape of a memorial to Snow." A drinking fountain on the Thames Embankment is the form of memorial proposed. The particular form is of little moment. What is wanted is that a memorial, a national memorial, or better still, a memorial by the whole civilization, shall be raised to the man who has made all civilization his debtor for life and well-being. What the medical profession can do, is to make a beginning. If that beginning be generously made, we shall not have many years to wait for an adequate memorial to a great medical name. What the American profession can do is to show that the work of Dr. Snow is not unrecognized on this side of the water, after the beginning by Sir Richard Quain has been made. We estimate that there are not less than two hundred of our physicians who are no strangers to Dr. Snow's claim for recognition and would gladly "lend a hand." Let us have a National Board of Health.

We are personally indebted to Mr. Ernest Hart, of the *British Medical Journal* for much of the quoted matter in this article.

New Law Regulating Practice of Medicine in Ohio. Feb. 27, 1896, a new law was passed in Ohio relating to the practice of medicine in that State. It provides for the appointment, by the governor, by and with the consent of the Senate, of a State board of medical registration and examination, consisting of seven members, the full term of service to be seven years. They shall be physicians in good standing in their profession. Representation is to be given on the board to schools of practice in the State as nearly as possible in proportion to their numerical strength in the State, but no one school shall have a majority of the whole board. The president and treasurer shall be members of the board; the secretary a physician in good standing in his profession, each to serve for one year.

The board shall meet in Columbus on the first Tuesday of January, April, July and October of each year, and at such other times as the board may appoint. Five members shall constitute a quorum. The books and register of the board shall be prima facie evidence of all matters recorded therein. No person, it is further enacted, shall practice medicine, surgery, or midwifery, in any of its branches, without first complying with the prescribed requirements. If a graduate in medicine or surgery, he shall, either personally, or by letter or proxy, present his diploma to the board for verification. Accompanying the diploma, he shall file his affidavit that the applicant is the person named in the diploma and is the lawful possessor of same, giving his age and the time spent in the study of medicine. If the board shall find the diploma to be genuine, and from a legally chartered medical institution in good standing, as determined by the board, and the person named therein the person holding and presenting the same, the board shall issue its certificate to that effect, which, when left with the probate judge of the county of his residence for record, shall be conclusive evidence that its owner is entitled to practice medicine or surgery in the State. If a legal practitioner of medicine under the laws in force at the time of the passage of this act, but not a graduate of medicine and surgery, as above defined, he shall furnish the board an affidavit stating the period during which and the places at which he has practiced medicine or surgery, and if the board shall be satisfied from the affidavit and other information received that he was a legal practitioner of medicine in Ohio at the time of the passage of the act, it shall issue its certificate to that effect, which when left for record, shall be evidence, the same as stated in the previous case. If engaged in the practice of medicine in Ohio at the time of the passage of this act, but not a legal practitioner under the laws then in force, nor a graduate in medicine or surgery as above defined, he shall present himself before the board and submit to such examination as to his qualifications as the board may require. The board's certificate to him, on passing a satisfactory examination, will only entitle him to practice for one year from date thereof. The board may refuse to grant a certificate to any person guilty of felony or gross immoral conduct, or addicted to the liquor or drug habit to such a degree as to render him unfit to practice medicine or surgery; and may, after notice and hearing, revoke a certificate for like cause; appeal being allowed, in either case, to the governor and attorney general, whose decision is final. Ninety days after this law takes effect is allowed all persons engaged in practice to comply with its requirements. An affirmative vote of not less than five members of the board is necessary for the issuance or revocation of a certificate. The fee for a certificate in either of the first two cases is \$5; on examination, \$25, a re-examination within a year being allowed the unsuccessful. Upon application, the probate judge shall make out a certified copy of any certificate and the indorsements thereon, which shall be prima facie evidence of all matters and facts therein contained. In case of a change of residence, the owner of a certificate must have the same recorded anew by the probate judge of the county into which he removes. Every person practicing midwifery in the State at the time of the passage of this act, shall within ninety days file with the probate judge of the county in which she resides, an affidavit giving her name, age, residence, the length of time during which and the place or places at which she has been engaged in said practice, and the special education, if any, which she has received to fit her for such practice. Thereupon, upon the payment of a fee of \$5, the probate judge shall issue a certificate which shall entitle her to practice midwifery. All persons desiring after the passage of this act to enter upon the practice of midwifery in the State, shall appear before the State board and submit to such an examination in midwifery as it shall require. Its fee for a certificate is \$10. A certificate to practice midwifery may be refused or revoked for the same

causes and in the same manner as a physician's certificate. It must also be recorded the same as the other. But a certificate granted to practice midwifery shall not give the holder the right to perform version, or treat breech or face presentation, or do any obstetric operation requiring instruments, or to treat any other abnormal condition, except in emergencies. Any person shall be regarded as practicing medicine or surgery within the meaning of this act who shall append the letter M.D. or M.B. to his name, or for a fee prescribe, direct or recommend for the use of any person, any drug or medicine or other agency for the treatment, cure or relief of any wound, fracture or bodily injury, infirmity or disease: provided, however, that nothing shall be construed to prohibit service in case of emergency, or the domestic administration of family remedies; and this act shall not apply to any commissioned medical officer of the United States army, navy or marine hospital service in the discharge of his professional duties nor to any legally qualified dentist when engaged exclusively in the practice of dentistry, nor to any physician or surgeon from another State or territory, who is a legal practitioner of Ohio, nor to any physician or surgeon residing on the border of a neighboring State, and duly authorized under the laws thereof to practice medicine or surgery therein whose practice extends into the limits of Ohio; providing that such practitioner shall not open an office or appoint a place to meet patients or receive calls in Ohio. The penalty for practicing medicine or surgery in violation of this act is a fine of from \$20 to \$500, or imprisonment of from thirty days to one year, or both, and for practicing midwifery without having complied with it, a fine of from \$25 to \$100. Any person who shall file, or attempt to file as his own, the medical diploma or certificate to practice of another, or shall file or attempt to file, a false forged affidavit of his identity, or shall wilfully swear falsely to any question which may be propounded to him on his medical examination, or to any affidavit required to be made or filed by him shall be imprisoned in the penitentiary not more than five years nor less than one year. Such fines when collected shall be paid, one-third to the person, corporation or medical society making the complaint or furnishing the information, one-third to the poor fund of the county, and one-third to the State board. The secretary of the board is charged with the duty of enforcing this act. If he have knowledge or notice that it has been or is being violated, he shall investigate the matter, and upon probable cause appearing, file a complaint and prosecute the offender. It shall be the duty of the prosecuting attorney, when requested by such secretary, to take charge of and conduct such prosecutions. Original sections 4403 and 6992 of the Revised Statutes of Ohio are repealed.

Practical Notes.

Electric Depilation.—After treatment of this kind there are always a number of hairs that grow out again, and Dubreuilh states that these are new hairs, supplanting a hair that was dead at the time of treatment. To save the useless trouble of electrolyzing dead hairs, he first has the surface cut close a week or so beforehand, and then electrolyzes only those hairs which have evidently grown since they were cut, merely pulling out with the tweezers those that have not grown. A few weeks later he electrolyzes the young hairs that have grown in the places of the latter.—*Annales de Derm. et de Syph.*, April.

Discussion of Treatment of Adenoid Vegetations.—At the Congress of the French Société de Laryngologie, Otologie et Rhinologie held at Paris recently, the old idea that persons subject to adenoid growths are deficient in intelligence, was disproved and the fact cited that Canova and Charles V were "adenoidans." Medication alone is absolutely ineffective. Digital palpation must accompany the use of the mirror, and the only contraindications to an operation are hemophilia, arterial anomalies and activity of adenoid growth. Washes were strongly con-

demned by the majority, and the use of an anesthetic by a few. Others urged its necessity as a matter of course and use hydrobromic ether. Texier stated that ten to fifteen grams are sufficient and no accidents follow the use of this small amount. Polo gives a few drops of ferric chlorid for a few days previously to prevent hemorrhage. Sea air is generally considered to have an unfavorable effect, and some cases were reported of otitis of the middle ear, following a stay at the sea shore.—*Bulletin Médical*, May 10.

Calomel in Heart Disease.—Maldarescu writes to the *Therap. Woch.* of May 10, describing the successful results he has obtained with calomel in heart troubles accompanied by distress in breathing, severe disturbances in the circulation, ascites, edema, albuminuria and hypertrophied heart and liver. He gives it in six powders with sugar, 0.10 gram every two hours during the day, for two or three days, following this with 0.10 to 0.20 gram a day for a few days, after when he then commences potassium iodid. Enormous ascites and edemas vanish with this treatment, and even patients in complete cyanosis are restored to comparative health. He ascribes the wonderful action of the calomel to its effect on the liver. It relieves the congestion, and thus restores the circulation in the important portal and liver veins, which exert a favorable influence on the entire circulation and cures some of the complications, while it relieves all. The gums are frequently affected by the calomel, and he orders a mouth wash from the first, consisting of potassium chlorate 10.0, tannin 0.25, aq. dist. 350. He limits his patients to a milk diet during the treatment, and warns them afterward to refrain from alcohol and excessive exertion, and restrict themselves to a light diet, and persist in the use of potassium iodid. He has treated 107 cases, with five deaths of those that were *in ultimis*, and nine other deaths, all of elderly persons in advanced stages. He notes that the calomel has also the advantage that after it other remedies produce their best effect. He scouts the idea that calomel can form sublimate in the alimentary canal, as a very elevated temperature is required for this.

Cincinnati.

THE COMMITTEE SELECTED by the State Board of Medical Examiners to investigate the American Eclectic Medical College, Hygeia Medical University of Ohio, and the Vitapathic College began their investigations June 11. Ex-Attorney-General John K. Richards and County Prosecuting Attorney Schwartz are conducting the examinations. It is stated that the American Eclectic Medical College has been blacklisted by the Boards of Alabama, California, Colorado, Illinois, Iowa, Kansas, Kentucky, Louisiana, Minnesota, Missouri and New Jersey.

DR. CHARLES H. CASTLE has resigned as resident physician of the Cincinnati Hospital to assume charge of the surgical clinic of the Miami Medical College, and has also been elected secretary of the faculty.

DR. CHARLES A. L. REED has been elected gynecologist and abdominal surgeon on the staff of the Cincinnati Hospital, vice Dr. T. A. Reamy, resigned.

THE FIGHT against the alleged abortionists is being carried on with commendable vigor.

THE OHIO STATE PEDIATRIC SOCIETY elected the following officers at its annual meeting held at Columbus May 27: President, Dr. S. W. Kelly, of Cleveland; Vice-President, Dr. J. P. West, of Bellaire; Secretary, Dr. George M. Clouse, of Columbus; Treasurer, Dr. J. M. Dunham, of Columbus. The next meeting will be held in connection with the Ohio State Medical Society.

THE MORTALITY REPORT for the week ended May 29 shows 107 deaths.

THE STATE BOARD OF MEDICAL EXAMINERS of Ohio have

passed the following resolutions in relation to the standing of medical colleges:

Resolved, That all medical colleges of the United States requiring a minimum of three years' study of medicine and two courses of lectures for graduation, prior to 1886, and possessing proper facilities for teaching and a faculty embracing the chairs of anatomy, physiology, chemistry, materia medica, therapeutics, medicine, surgery and obstetrics shall be recognized as in good standing, and diplomas issued by the same and properly verified shall entitle the holders thereof to register as graduates in medicine under the laws of Ohio, providing that no certificate shall be issued to any applicant upon proof that his or her diploma has been obtained fraudulently, or in violation of the published rules of the college issuing same.

Resolved, That for the ten years ending Feb. 27, 1896, all medical colleges exacting the foregoing requirements and possessing facilities and a faculty as specified in foregoing resolution shall by virtue of such facts be recognized as in good standing to and including the year 1892, but that no medical college shall be recognized in good standing which has not since 1892 possessed the foregoing facilities and faculty, and which had not in addition exacted an entrance qualification and attendance upon three regular courses of lectures as a condition of graduation.

Resolved, That on and after July 1, 1899, no medical college shall be recognized as in good standing which does not require the entrance qualification prescribed by the Association of American Medical Colleges as a prerequisite for matriculation: which does not possess an adequate equipment for teaching medicine: which has not clinical and hospital facilities, based upon a minimum municipal population of 50,000, and which does not have an active faculty embracing the departments of anatomy, physiology, chemistry, therapeutics, materia medica, medicine, obstetrics, histology, pathology, bacteriology, gynecology, laryngology, hygiene, state medicine, surgery, ophthalmology, and which does not enjoin attendance upon 30 per cent. of four regular courses of instruction, of not less than twenty-six weeks each in four different years, and which does not exact an average grade of 75 per cent. on examination as conditions of graduation; providing that the rule relative to population as a basis for clinical and hospital facilities shall apply to institutions under State control, receiving gratuitously patients from all parts of the State in which the colleges are located.

Washington.

WEEKLY REPORT OF HEALTH OFFICE.—The report of the Health Officer for the week ending May 23 is as follows: Number of deaths (stillbirths not included), 83; death rate per 1,000 per annum, 15.7; death rate per 1,000 per annum for the corresponding week last year, 15.2. A fall of over 16 per cent. in the mortality of the city occurred last week as compared with the week before. The improvement was mainly in a decrease in the diseases of the respiratory organs and of the mortality among children under 5 years of age.

LAW REGULATING TESTIMONY OF PHYSICIANS.—"That in the courts of the District of Columbia no physician or surgeon shall be permitted without the consent of the person afflicted, or of his legal representative to disclose any information, confidential in its nature, which he shall have acquired in attending a patient in a professional capacity and which was necessary to enable him to act in that capacity, whether such information shall have been obtained from the patient or from his family or from the person or persons in charge of him: *Provided,* That this act shall not apply to evidence in criminal cases where the accused is charged with causing the death of, or inflicting injuries upon, a human being, and the disclosure shall be required in the interests of public justice." The above became a law without the signature of the President. To obviate this law some of the life insurance companies have incorporated the following in their contract for insurance: "I also agree to waive all provisions of law forbidding any physician or surgeon from disclosing any information acquired while attending me in a professional capacity."

PHYSICIANS TO THE POOR appointed by the Health Officer: Drs. Taliaferro Clark, F. A. Mazzei, D. G. Lewis, P. O. Roman, J. A. Stoutenburg, E. M. Hashbrouck, E. E. Richardson and G. W. Wood.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from May 30 to June 8, 1896.

Capt. Louis A. LaGarde, Asst. Surgeon U. S. A., is granted leave of absence for one month.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending June 6, 1896.

Surgeon L. L. von Wedekind, ordered to the Naval Academy.

Surgeon C. A. Siegfried, detached from the "Columbia" and ordered to the "Massachusetts."

Surgeon E. Z. Derr, detached from the "Raleigh" and ordered to the "Columbia."

Surgeon H. G. Beyer, detached from the naval academy June 5, and ordered to the "Raleigh" June 6.

P. A. Surgeon M. S. Gnest, detached from the "Constellation" June 8, and ordered to the "Massachusetts" June 10.

Marine-Hospital Changes. Official list of changes of station, and duties of Medical Officers of the U. S. Marine-Hospital Service, for the sixteen days ended May 31, 1896.

Surgeon J. B. Hamilton, granted leave of absence for ten days, May 23, 1896.

P. A. Surgeon B. W. Brown, granted leave of absence for six days, May 25, 1896.

Asst. Surgeon C. H. Gardner, ordered to examination for promotion, May 27, 1896.

BOARDS CONVENED.

Board convened to meet in Washington, D. C., June 15, 1896, for the examination of officers for promotion and candidates for appointment in Service. Surgeon G. W. Stoner, chairman; Surgeon Fairfax Irwin and P. A. Surgeon C. E. Banks, recorders, May 25, 1896.

Board convened to meet in New York city May 27, 1896, for the physical examination of candidates for appointment in revenue cutter service. Surgeon W. A. Wheeler, chairman; P. A. Surgeon J. H. White, recorder, May 25, 1896.

U. S. Indian Service Changes. Medical Department, Z. T. Daniel, M.D., Agency Physician.

Pine Ridge Agency, South Dakota, to U. S. Indian Industrial School, Carlisle, Pa.

Change of Address.

Beadles, C. H., from Lewiston, Ill., to Sadlersville, Tenn.

Berry, H. A., from Chicago to Oswego, Ill.

Davis, R. E., from Chicago to Wales, Wis.

Dick, D. B., from Mt. Pleasant to Oakville, Ill.

Dvorak, W. R., from 1811 W. 16th St. to 1620 W. 22d St., Chicago.

Fuller, Wm., from 4704 State St. to 4700 State St., Chicago.

Grote, H. W., from Chicago to Room 9, Masonic Temple, New Orleans.

Hollister, Thos. C., from Pawnee City, to Louisville, Neb.

Hall, L. T., from Fulton to 911 N. Vandeventer Av., St. Louis, Mo.

Jackson, Edward, from Denver, Colo., to 1633 Locust St., Philadelphia.

Kelly, Warren, from Carlisle to Traskwood, Ark.

Kilpatrick, O. B., from New York, N. Y., to Cherry Fork, Ohio.

King, Elliott R., from Muscatine to Wilton Junction, Iowa.

Moody, G. H., from Mexico to South Texas.

Monette, Geo. N., from 5 Prytania St., to 1620 Calliope St., New Orleans.

McGahan, C. F., from Aiken, S. C., to Bethlehem, N. H.

Rhoden, J. C., from Chicago to P. O. Box 63, Ponca, Neb.

Seagley, I. B., from 936 Polk St., to 627 Grand Av., Chicago.

Sigle, Emma, from Chicago to Hales Corners, Wis.

Smith, Col. J. R., from Government Island, N. Y., to 2135 Spruce St., Philadelphia, Pa.

Wood, E. S., address should be 524 Michigan Av., Leavenworth, Kan., instead of Chicago.

ORIGINAL ARTICLES.

CHOLELITHIASIS AND CHOLELITHOTOMY.

Read in the Section on Surgery and Anatomy, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY CHAS. H. DUNN, M.D.

MINNEAPOLIS, MINN.

My paper, of which I beg to present a partial summary, is based upon a study of some forty cases of gallstone disease and a review of the chief literature of the subject. The personal observations concern eleven cases upon which I operated, comprising: One cholecystectomy; one choledochotomy; two cholecystenterostomies; six cholecystotomies with temporary fistulae; one cholecystotomy by long drainage button; four autopsies in deaths from cholelithiasis without surgical interference; eight cases which for various reasons were not subjected to operation, in which the diagnosis was confirmed by passage of gallstones, and sixteen cases in which a diagnosis of gallstone was more or less positively made, but not confirmed by recovery of the calculi either by operation or in the stools.

In the course of this brief experience I have been strikingly impressed by several facts, among which may be noted: The highly overdrawn notion of biliary colic and a misinterpreted view of the symptomatology of cholelithiasis prevalent in the general professional mind; the mistaken prominence given to jaundice as a symptom, and the tenacity with which a childlike pathology explaining its presence or absence in the purely mechanical action of the stone is held; the readiness with which a phenomenal (and it might seemingly be thought an astonishingly unexpected) latency of gallstones is on all hands admitted without dissent, though this dogma when scrutinized rests upon evidence little better than bad logic, viz., so many people are found after death to have had gallstones who made no complaint about them during life.

The mechanics of the profession appears to have been thrown completely into our pathology: for the average practitioner often pursues persistently for months and years his very unmechanical as well as irrational treatment. If indications and contraindications for interference are in some diseases more numerous than usefully set forth, our brochures on this topic are often singularly silent or those given appear strangely farcical, *e.g.*, as given by one German authority, the size of the concretions.

When surgery is at last reached it has seemed to me that the mind is too often occupied with this or that set method, rather than with a determination to seek actual conditions and best meet them. In proof of this I need but say that when Murphy brought out his wonderful button too many of us went to making cholecystenterostomies in cases neither demanding nor

justifying cholecystenterostomy, thus putting a grand good thing to base uses.

It is becoming better understood that jaundice is a comparatively infrequent symptom, at least in the earlier course of the average cholelithiasis, and that cases frequently run their whole course even to a lethal ending without icterus. Riedel has long since shown us that the jaundice is very often due to catarrh of the bile tracts, the result of infection rather than to the impaction of stones. Yet I believe we still give too much credence to mechanical impaction as a cause of jaundice. I herewith report the autopsy of a young and otherwise healthy woman who died as a result of a six weeks attack of biliary colic, with nearly constant pain, tenderness and vomiting. She had had but one previous attack and that of short duration nearly one year before. Aside from these two attacks her health was perfect. There was a trace of bile present in the urine, but at no time had there been a trace of icterus observable by friends, trained nurses, or physicians. The stools were not clay colored.

The patient first came under my observation a week before death. A diagnosis of cholelithiasis was made and operation advised despite the terribly exhausted condition of the patient. Surgical interference however was refused by her friends. At the autopsy five gallstones—each about three-eighths inch in diameter were found, these being located in the gall bladder and two impacted in the common duct at the ampulla of Vater. The stone nearest the intestine appeared to be immovably fixed, the duct dilated to the size of my little finger. Yet this astonishing state of affairs did not prevent the bile from passing between the dilated duct walls and the stone. There can be no doubt but a moderate swelling of the mucosa of the tract would have closed the small calibred opening through the duodenal walls, or have closed the dilated walls about the stone and rapidly obstructed the biliary flow. I believe that the icterus which often accompanies cholelithiasis is due even in larger measure than any of us have yet conceived to inflammatory changes in the bile tracts and but in very small measure to the simple lodgement of calculi in the common or hepatic ducts. At any rate the presence or absence of icterus must not too strongly influence us as to the location of the stone.

It seems to me that we are in need of some relatively fixed notions as to the indications pro and con for surgical interference in this affection. Perhaps very few of us would regularly advise cholelithotomy as soon as a diagnosis is made. Though such a course is, in my opinion, open to many objections, it would be doubtless preferable to the one so often chosen, *i.e.*, floating along by guess and by chance until the patient requests operation as a relief from unbearable suffering, or because he is clearly in imminent danger of death. Though I believe the percentage of per-

sons who have suffered severe attack of biliary colic without surgical means, is not very large, yet spontaneous or medical cures must be admitted. The discomforts and dangers of individual cases vary greatly. It would therefore seem that our indications for cholelithiasis ought to be divided into relative and inoperative. In operating upon relative indications, good sense ought to be used and circumstances well considered.

If the attacks be frequent, the calculi not present and the symptoms be unrelieved by a reasonable hygienic and medical course of, at most, a few weeks' duration, so safe an operation as cholecystotomy at this stage, under proper hospital and modern operative advantages, is doubly preferable to further delay, even though no very threatening symptoms have developed. First, as the easiest escape from present suffering; second, as a preventive measure against the ever possible dangers of cholangitis, duct impactions, etc., which may entail a much more dangerous and trying operation upon a patient hardly able to bear any surgical interference.

I am firmly convinced that we shall in time come to see that the proper treatment of active cholelithiasis, with few exceptions, is early surgical interference. Nevertheless, so long as the patient is in no evident danger, a rational management may be tried through one or several attacks, as good judgment may dictate. For biliary or renal colic may be severe or repeated without indicating that natural cure is impossible, provided the engagements be short and decisive, uncomplicated by infection, and the peace, however short, fairly complete. But when, after several days' duration, only partial peace is declared, the general health begins to fail, local tenderness persists, lesser paroxysms recur and jaundice threatens, operative interference may, for practical purposes, be said to be imperative. The practical distinction between relative and imperative indications in surgery is of the greatest importance, and unfortunately too often overlooked. Imperative indications justify operation under conditions which might be almost criminal in the presence of only relative indications.

It seems to me a very pertinent question whether or not operation should be advised in the midst of a recent attack of colic. Kehr, having, as he believes, learned to distinguish between gall bladder colic and gall duct colic, advises waiting when the latter exists, lest the stone be left in the choledochus or a difficult choledochotomy need to be performed. But most of us will be often quite unable to make this differentiation with any certainty, while to delay long with a calculus in this most dangerous locality will often jeopardize the patient. Presumably he means to advise against immediate interference in the midst of an acute biliary attack, while a stone may be supposed to have advanced deeply into the choledochus without having time to be expelled. In this form the advice is clearly wise. Had the case referred to been operated upon hastily the night before the stones passed, it is not improbable that one might have been left in the duct, if not removed at the expense of a more serious operation than ordinary cholecystectomy. But, as already stated, it is chiefly disagreeable repeated minor attacks of gall bladder colic or the failing health due to incompletely relieved attacks which call for surgical decision. Effectual expulsive attacks are mostly decisive in a few days at most, for when a stone remains longer impacted, the ducts are soon

dilated, expulsive power is lessened, as evidenced in less severe and decided paroxysms, and the stone is usually left in undisputed or feebly contested possession of the field. The diagnosis once positively made, it would appear less difficult for a surgeon of sense to approximate reasonably the burdens and dangers of the disease in a given case, to distinguish when to advise waiting, when to recommend operation and when to insist upon it, than to formulate rules for others. In such matters hard and fast rules are absolutely irrational. Infinite certainty can not be achieved. Probabilities are the rule of life, and remain here the only and safest guide. If in certain cases delays are advisable, in others, like Case No. 7 of ulceration of the gall tracts, the first attack may call for prompt action. One prominent authority seems to regard the size of the concretions as having an important bearing upon operative indications. To my mind this is an evidence of the tenacity with which we unconsciously cling to the mechanical interpretation of calculous disorders, even after we ought to know the pitfalls of this childlike pathology. In the first place, we can foretell absolutely nothing as to the size of the stones before they are removed or passed. In the second place, however much the theory that a small stone ought and that a large stone can not be passed may appeal to rational simplicity, my last case proved to me that facts fail to follow mathematical fancy. This young woman had suffered for one and a half years, until almost tired of existence, from severe and frequent colics, yet the stones on removal were astonishingly small, the great majority being the size of apple seeds, and none larger than a pea.

Even a limited experience in cholelithiasis leads one to appreciate the variety of the conditions liable to be encountered, and to recognize that a variety of operative technique is required to meet the demands of different cases. Yet there must be procedures of preference. All modern observation goes to show that nine times out of ten, the gallstones occupy the gall bladder alone. Ninety-five times out of one hundred they occupy the gall bladder alone or it and the cystic duct alone. Such a bladder is frequently deeply and generally more or less diseased. In the vast majority of cases, therefore, the indication appears to be, to open the gall bladder, remove the stones and debris, and temporarily drain the diseased organ. After the most careful evacuation stones, sand or fragments are sometimes left, and thus the temporary drainage insures against recurrence.

I therefore believe that cholecystotomy with temporary fistulae is the operation of election in the average cholelithiasis, the one to be chosen probably eight or nine times out of ten. In the remaining minority a variety of less usual circumstances, whether inherent in the anatomy or condition of the patient, in local changes in the gall tracts or location of the stones, etc., demands a modification in the operation. Thus, when the gall bladder, as in my Case No. 3, is atrophied to a mere rudiment, or sloughing, cholecystectomy is rational, otherwise I can see no reason for removing this organ. On the other hand, when ducts are impacted with stones, it is perfectly clear that complete removal of the stones is the great and ideal desideratum, choledochotomy added to the operation already advised. Under such circumstances, if manipulation and crushing fail to empty the impacted ducts, the next choice is choledochotomy.

Happily, impaction in the common and hepatic ducts is much rarer than many suppose. The highest estimates place the proportion of common duct impactions at less than 4 per cent., and of the hepatic in less than 1.5 per cent. of cholelithic cases. But choledochotomy is always difficult, frequently dangerous and sometimes impossible of practical execution.

DISCUSSION.

DR. DONALD MACLEAN—What I have heard has impressed me with the belief that has been gradually growing in my mind for a good while and that is that there is a great and magnificent field for surgery in connection with the gall bladder and the gall ducts. I believe that that department of surgery is in its infancy, and there is this to say for that department, in contrast with ovariectomy, hysterectomy and other operations of that kind, that it is altogether conservative. If you save your patient you do not save a mutilated and more or less unhappy human being. If you secure a success in an operation of that kind the patients get well and has the satisfaction of feeling that they are relieved from a painful, dangerous and distressing disease and that they are just as good as they were when they first started in life. There is a great difference between this department and those of a mutilating and injurious nature. I do not mean to say anything against the removal of ovaries, uterus and testicles where it is necessary to do so. There will always be this hopeful and inspiring feeling about operations on the gall bladder, that is, if you save your patient from great pain and great danger, and the patient gets well, there is everything to be gratified about and nothing to regret. I believe that there is a vast field for surgery in this very direction, and it is my opinion that, as far as the surgery of the gall bladder and gall ducts is concerned, it is, as I have said before, only in its infancy. As the time goes on and experience accumulates the surgery of these organs will ultimately show grander and more satisfactory results than the surgery of any other organ.

DR. ALEX. HUGH FERGUSON, Chicago—Cholelithiasis is not a medical subject but a surgical one. These cases are rarely affected by the efforts of nature and usually resist medication. That being the case the question is when shall we operate? Let us picture a few of the clinical phases. First the patient may be seized with colic with or without jaundice. Having this colic and jaundice you examine the gall bladder and you will find it enlarged and the cystic duct obstructed. Mucus flows in and the gall bladder becomes enlarged so that apparently there is a tumor there. This is the time to operate as you have seen the case early and you can select your own operation. The operation of election is to communicate with the gall bladder externally. The cases often commence with colic and you then have this enlargement over the gall bladder. After this the stone falls back into the gall bladder, the attack is over and shortly thereafter the patient will have another attack. Jaundice then develops and this is a graver symptom than colic. The stone is now impinged upon the common duct and you have obstruction. If the stone be a small one it may pass through, but if not, it may force its way into the common duct, where it becomes stuck and dilates this duct. Subsequent attacks will occur and then the gall bladder contracts. When the stone is in the common duct the gall bladder becomes obliterated, and I know of one case in which I could find no gall bladder. The cases of one stone are more difficult than those where there is a large array of stones. The size of the gall bladder is no indication, and you can not tell whether the stones were passed through or not. You may find a gall bladder filled with stones that have not passed down. They may have become attached to each other. Then again you may find a number of stones of various sizes. How can you tell whether or not the stones are going to pass through? If the patient has colic and jaundice it is imperative to open the gall bladder, otherwise the next symptom will be pyrexia. If you wait until this what does it mean? That we have another complication. The stones have entered the lining mucous membrane and the germs have found an entrance into the denudation. These are difficult cases and no case should be left until pyrexia takes place. Long continued jaundice may occur in cholelithiasis. It is these cases that exist for months or years that are characteristic of a stone in the common duct as compared with the jaundice which takes place in malignancy. The stone in jaundice floats backward and forward and occasionally some bile gets down which keeps the patient alive.

The surgery of the gall bladder is pretty well settled, and the operation is to open it and communicate with it externally. How will you do it? By attaching the gall bladder to the peritoneum and skin and suturing them together has been mentioned, but it must be remembered that 33 per cent. of these operations have resulted in permanent fistulae. That was the objection of Murphy when he invented his wonderful button. If we perform cholecystotomy properly why not attach the gall bladder to the peritoneum? It should be united to the upper and not to the middle and lower portion. It will naturally form slight peritoneal adhesions. If the formal opening has been done away with and it has been drained, for the time being there is no further use for it. Stones may be situated in the enlarged gall bladder, and if there are a number of them they may get by the gall bladder, the cystic duct and the hepatic duct. Now as to the jaundice. Jaundice cases are difficult to operate on as they stand the operation and the chloroform very badly. Beside this, hemorrhage may occur and our duty in these cases is plain, do as little operating as possible. Try to tide the patient over from being killed with the jaundice. As soon as we unite the gall bladder to the peritoneum and clear out the gall bladder and hepatic duct, and if we can with proper curets clear out a little further our object is done. As soon as we see bile our work is over. We know that after we do that stones will follow and the common duct and hepatic duct will clear up. All that is necessary is for us to unite the gall bladder to the external wound. The most difficult surgery of the gall ducts is obstruction of the common duct, the operation for which is the opening of the duct or choledochotomy. In all of these cases when the stone is situated in the upper two-thirds of the common duct it is clear that an external operation must be done. There are two ways of getting at the common duct, one external and the other internal to the duodenum, of which the former is the better. If you have jaundice the incision should be either oblique or transverse and I think the oblique gives more room. As we pass our fingers in we find we are able to get two fingers into the foramen of Winslow. The common duct is nearest to us and this is the best way of opening it. You then separate the duodenum and you may have to dislodge it. Remove the stone if you can, and very frequently you can feel it *in situ*. The greatest difficulty is when the stone is impacted just at the opening of the duodenum. What we should do then is not quite clear. You might open the duodenum but how shall you know whether the common duct is patulous or not? This is very difficult to tell. A good way is to take a glass tube that is bulbous at the end with a rubber bulb attached to it. This will become impinged in the duct. You fill the bulb with water and you ascertain whether this water will flow through or not. If it will, I stop operating.

DR. J. C. OLIVER—Dr. Dunn reports a case of a healthy young woman who had attacks of biliary colic without jaundice. I would like to ask what was found to be the cause of death at the autopsy.

DR. HUNTER MCGUIRE, Richmond, Va.—I was very much interested in Dr. MacLean's remarks on this subject. It has been worth the trip down here to listen to the address delivered by Dr. Osler this morning, in which he criticised the medical treatment of years ago. I sometimes wonder what surgeons will say of us a hundred years from now. With regard to Dr. Dunn's operation, I feel a little anxiety about it. I believe that after awhile some one will stumble upon a way of dissolving gallstones so that operation will not be necessary. By this time the gentleman who suggested castration for prostatic enlargement will not wish to see the operation performed.

DR. DUNN (in closing the discussion)—I have not much more to say. With regard to the young lady referred to by Dr. Oliver, she died of exhaustion. She was unable to keep anything on the stomach for six weeks and she simply died. I was sorry to hear Dr. Ferguson speak of the tumor symptom of gall bladder disease. I took much pains to find fault with the ideas that have been so prevalent in the profession as to the diagnosis of gallstone disease but I did not refer to it in my paper. A good many country fellows, like myself, when we read in ordinary books, get an idea that there should be jaundice or tumors or colic resembling the pains of childbirth. My paper was not intended to tell anything wonderful about gallstone operations. We already have plenty of technique and what we need is a little diagnosis. I have not found the tumefaction in any cases. If enlargement of the liver dullness is meant by tumefaction it is very frequently present, but I think we already have in our minds too much of an idea of the enlargement of the gall bladder as a symptom of cholelithiasis. Sometimes this not only is not enlarged, but one of my patients dies without this enlargement. If a tumor was present it was independent of the distended gall bladder.

THE TECHNIQUE OF REMOVING THE APPENDIX VERMIFORMIS CECI: REPORT OF ONE HUNDRED CASES.

Read in the Section on Surgery and Anatomy, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY M. M. JOHNSON, M.D.

HARTFORD, CONN.

Intestinal surgery has, within the last few years, received a long-needed attention. The correct diagnosis of the diseased condition of the appendix, and its operative treatment, has demonstrated the great possibilities of intestinal surgery. As a result we are now saving a class of patients which we have been unnecessarily burying all these many years. As there is a great diversity of opinion as to operative technique it affords a fertile field for our careful consideration.

Preparation for the Operation.—The patient should receive a general bath in which he is thoroughly washed with a flesh brush and green soap and water, as hot as can be comfortably borne. The abdomen and pubes are shaved, and a green soap poultice applied from two to six hours, followed by a washing with sterilized water, to remove the epidermis which has been acted on by the soap. A towel, wet with 1 to 1,000 solution of bichlorid, is applied until the time of the operation. When upon the table the skin is bathed with ether and alcohol, and covered with a sterilized towel. Patient is now ready for the operation.

The nails of the operator and the assistant should be short and smooth, their hands and forearms should be washed with soap and water, and with a brush for five minutes. After rinsing with sterilized water, they are immersed in 1 to 1,000 bichlorid solution for ten minutes. This method of hand disinfection has stood the test of bacteriologic examinations. When a more hasty preparation is required, permanganate of potash and oxalic acid are used, according to Holsted.

All dust in the operating room should be removed with a cloth wet with bichlorid solution. As operations frequently have to be performed in an uncleanly house, all dust and dirt in the room, on the furniture, etc., should not be disturbed before the operation. Place a washtub in the middle of the room, and pour boiling water into it. The steam will soon moisten the dust so it will fall to the floor, and the germs with it. You have then a pure atmosphere in which to operate.

Instruments should be sterilized by boiling. Instrument trays should be placed in boiling water, or filled with 5 per cent. solution of carbolic acid. Sponges should be discarded. Sterilized gauze is much safer. All dressings should be wrapped in sterilized towels ready for use when wanted. Care in these minor details is all important.

The Incision.—Surgical opinion as to the length of the incision varies from one and one-half inch to seven or more inches. When we take into consideration the future welfare of the patient, a condition which can not be overlooked by the surgeon, whether the patient be a manual laborer or a brain worker, in either case he is entitled to as firm and sound abdominal wall as can be secured. The shorter the incision, the shorter will be the time the patient must remain in bed, and the more secure will the abdominal walls be. The much criticised statement of Dr. Morris, "An inch and a half a week and a week and a half," contains a sound surgical principle.

While we know that a seven inch incision will unite as soon as an inch and a half, we also know that, with a short incision, the patient will be in a safer condition to leave his bed in from ten to fourteen days, than the one with a seven inch incision will be in six weeks. In fact, with a long incision, it is a question if the patient will ever be secure from a ventral hernia.

Another very important point is, that the intestines should be manipulated as little as possible.

The shock to the patient and the severity of the colicky stage following the operation, is in proportion to the degree of manipulation to which the intestines are subjected. With a long incision, the escaping intestines protected with a towel are exposed to the air, oftentimes becoming more or less chilled. Much manipulation is required to return and retain them within the abdominal walls. The chance for sepsis and the looping or twisting of the intestines is also great.

In chronic recurrent cases, the writer makes an incision one and one-half inches long directly over the appendix, which has been previously located by palpation, and sufficiently oblique to follow the fibers of the external oblique aponeurosis. When the peritoneum is reached, a catgut suture is passed through it at the upper angle of the incision, before it is cut through. This prevents its retracting and is of material aid in stitching the edges of the peritoneum. This is what Dr. Morris calls his "guy line" device. In complicated cases, the length of the incision must be determined by the room required. I find it best to commence with a short incision and then enlarge as it is necessary.

Method and Complications in Finding the Appendix.—The incision made, the problem of finding the appendix presents itself. Passing the thumb and index finger through the small incision, one quite readily seizes the colon, which is distinguished by a longitudinal muscular ribbon, which is drawn through the incision and returned to prevent exposure, until the appendix is brought into view. The meso-appendix is ligated and incised. When the appendix is thus readily found, the problem is solved.

The position of the appendix is difficult to define. It may be attached to an old hernia sack, to the right ovary or the under surface of the liver. This latter condition the writer found in his 25th case. The work was much simplified by producing peristalsis by Morris's method of applying a minute quantity of sodium chlorid to the colon, which causes the peristaltic wave to run toward the appendix. Following this guide, the appendix was found adherent to the under surface of the liver. The adhesions were separated with the index finger, and the appendix removed.

When the cecum is surrounded with a pus sack, we usually find a perforated and sloughing appendix, which should be removed.

In another case the writer found the appendix detached and loose in the pus sack, the stump of which was later the source of a fecal fistula, which was successfully closed by a double row of Lembert sutures.

In still another class of cases, we find a large, hard mass of infectious exudate surrounding the appendix. It is all important to break through this mass, and remove the appendix. There is little danger from hemorrhage, it seldom occurs. This done, your patient is safe. It should be a fixed rule never to close up the incision without finding and removing the appendix,

otherwise your patient is in just as much danger as though the operation had not been performed.

Treatment of the Stump.—When the appendix is incised, the treatment of the stump resolves itself into the treatment of an intestinal perforation, which it in reality is. The surgical rules for the treatment of this condition should not be violated in treatment of the stump, viz.: Two infectious mucous surfaces should be turned in and not brought together, the object being to close the fistulous opening and prevent abdominal sepsis. Following these rules, one would suppose that all surgeons would adopt about the same method. On the contrary, Dr. Robt. H. M. Dawbarn of New York, says (May number of *International Journal of Surgery*, p. 139) that eleven different methods are in use by leading surgeons, all violating these rules to a greater or less degree.

The methods which have been most generally used, may be stated as follows: 1. Incising the muscular coat, and removing it. 2. Sterilizing the stump either by Paquelin cautery, or else chemically by fuming nitric acid, or rubbing with a bichlorid of mercury tablet, or applying a drop of carbolic acid. Whichever of the foregoing processes of disinfecting may have been adopted, they have been followed by the burial of the stump beneath the peritoneum of the cecum.

While these methods are popular, they are at variance with correct surgical principles, as they leave a point of infection in the peritoneal cavity, which will sooner or later prove a serious complication. As Dawbarn wisely says: "What would be thought of a surgeon who would treat a small penetrating wound of the gut by tying a string around it, leaving two foul and infected mucous surfaces tied together?"

The various chemicals used to disinfect the stump before burying it, cause a destruction of tissue. Hence, no healing can take place between two surfaces of dead tissue.

Dr. Dawbarn's method is surgically correct, and fulfills all the conditions with the greatest safety, and is the only method which should be used, the details of which are familiar, as they have been published in the journal referred to, and in others.

Closing the Incision.—In doing this important part of the work, we are justified in assuming that the various layers of tissue are arranged in the best possible order. We will respect the work of nature by leaving them as nearly as possible as we found them. We will return and pick up the "guy line" which we passed through the peritoneum when making the incision. By making gentle traction, the retracted peritoneum is brought into view in the upper angle of the incision. With a Martin needle loaded with No. 2 catgut, a stitch is easily passed through the free borders of the peritoneum and the edges drawn together. Remove the "guy line" and with a gentle traction on the last stitch enough of the peritoneum is drawn into the incision to easily take another stitch. This is continued until the peritoneal incision is closed by a continuous catgut suture. The transversalis fascia and transversalis and internal oblique aponeurosis is secured by a continuous suture, separately. The skin is put hard on the stretch by a tenaculum placed in the angle of the incision. The edges are united with No. 0 catgut in a fine needle, care being taken not to include any of the subcutaneous cellular tissues. This method restores the abdominal walls to their original firmness. I have not had

a case of hernia following this method of closing the incision. The writer uses catgut throughout the entire operation. It is the ideal suture and ligature, if it is properly sterilized. This latter condition can only be secured by buying the raw catgut and doing your own sterilizing.

As an illustration of the advantage of the short incision, the writer gives the following case: Sept. 18, 1895, Mrs. C. M. C. consulted me relative to a severe pain in the right iliac region. She was three and a half months pregnant, aged 25, primipara. She gave the history of having had two distinct attacks before her marriage and pregnancy. Examination revealed great tenderness and pain over the appendix which could be distinctly felt as it was much enlarged. I advised an operation which was performed at Water-nook Sanitarium, Sept. 24, 1895. The appendix was found to be much inflamed and was bound down by strong adhesions. The adhesions were broken up and the appendix removed. The stump was treated by Dawbarn's method. The incision was one and a half inches long. Patient made an excellent recovery and returned home in two weeks. I attended her at full time. She was delivered of an eight-pound daughter. The cicatrix did not yield perceptibly to the strain of pregnancy and parturition.

After-Treatment.—The patient is placed in bed, wrapped in a warm flannel blanket, with a hot water-bag at the feet. An enema of strong black coffee is administered in cases of much exhaustion. Small portions of hot water are given for the first twenty-four hours.

As we previously mentioned, we usually have an arrest of peristalsis following the operation. As a result, the bowels are greatly distended with gas, causing distressing colicky pains. Hypodermic injections of from 1-50 to 1-30 grain of strychnin are given once in four hours. This acts on the motor centers and hastens the return of peristalsis, with the result of throwing off the gas. Meanwhile, salol is administered to arrest fermentation.

When the bowel is distended for a long time the muscular coats become exhausted and the pain greatly increased. To guard against this condition, large injections of warm water are given per rectum; the gas escapes freely with the water, greatly to the relief of the patient, giving rest and relaxation to the muscular coats of the bowel. This flushing is repeated as often as it is necessary. By this treatment the colic period is shortened.

It is evident that the administration of an opiate is not a rational treatment for this condition. Opiates arrest peristalsis, the very condition we wish to overcome. Many deaths are no doubt due to the free use of opiates. A cathartic of magnesia sulphate is administered the following morning. When the bowels have moved freely, our patient goes on to a rapid convalescence.

In strongly septic cases due to pus, perforation, gangrene, etc., the wound is left wholly or partially open. A wick drainage of sterilized gauze wrapped around by gutta-percha, is inserted to the bottom of the wound. The gutta-percha covering prevents the granulations forming in the meshes of the gauze, rendering it so painful and difficult to remove. This drainage has a great advantage over the method of packing the wound with a large quantity of iodoform gauze.

The gauze, moistened with the saline solution, is

placed over the wound. The capillary attraction sucks up the serum, pus and other secretions through the wick drainage, sometimes in a large quantity. A layer of cotton is placed over all, and strapped down. The gauze should be removed in about twenty-four hours. A sterilized glass tube should be carefully inserted to the bottom of the wound, through which it is freely irrigated with the physiologic saline solution. This may be repeated three or four times daily. Hydrogen dioxid should be used once or twice a day to disinfect the wound. Following this treatment, at the end of a week, we usually have an aseptic condition. The patient goes on to good recovery.

When perforation is present, the bowel is frequently in such a softened and diseased condition that union will not take place if the perforation is closed. Many times by waiting a few months the coats of the intestine will have regained a healthy condition, so a successful operation can be performed. In other cases, a section of the bowel is in a gangrenous condition. Only one thing remains to be done: Remove the diseased section and unite the ends with the Murphy button.

Multiple Pus Sacks and other Complications.—We occasionally meet a class of cases characterized by a high grade of infection, multiple pus sacks rapidly forming with a gangrenous perforated appendix as the center of infection. It is this class of cases which tries the skill and courage of the operator. When the abdomen is opened, a most offensive pus flows freely. The appendix is firmly bound down in the pelvic cavity by strong adhesions. Around it is built the wall of the pus sack. The infection has spread beyond this, and other pus sacks are found. It is in this class of cases that we find a great diversity of opinion as to what should be done. We will quote what Gilbert Barling, M.B., F.R.C.S., Professor of Surgery in Mason's College, says (*British Medical Journal*, p. 1254): "When the pus is evacuated, the finger enters and searches for the appendix. It is often not recognizable, and if it is, it will almost certainly be firmly tied down by adhesions and no attempt should be made to remove it. Stripping out the appendix from the wall of the abscess is likely to break through the latter into the belly cavity, and lead to disaster. If the vermiform appendix is left, little anxiety need be felt as to future attack of appendicitis. They rarely occur."

Barling's opinion means, that little anxiety need be felt when we leave dead, decomposing, highly infectious animal tissue in the abdominal cavity. A more dangerous opinion could not be expressed.

I will relate a case which will illustrate the phase of the subject. It is one in which Dr. F. W. Chapin of Springfield, Mass., and myself were associated. At my request, Dr. Chapin operated, and I assisted him. The technique of the operation was the result of a mutual discussion of the case, and the writer assumes an equal responsibility. The lesson to be drawn from this case is too important to be omitted, as it embodied so many serious complications, viz.: pus; perforation, gangrene adhesions and secondary operation.

I first saw the patient, R. M. (a returned missionary), May 6, at my office. He had great pain and tenderness over the appendix. I advised an immediate operation, but the patient had a volume of reasons why it should not be done. Two days later there was a well-defined tumor at the McBurney point. I urged an operation, but without avail. May 10th the pain

was severe, the tumor much increased in size. I then told him emphatically that I could only save his life by an operation. I was then moving my private hospital, and had no place to take him. Dr. Chapin kindly took him to a private hospital in Springfield. May 12 the operation was performed by Dr. Chapin. The incision was made over the tumor, a large abscess was opened and thoroughly irrigated with physiologic saline solution followed by the hydrogen dioxid. A fecal concretion was found in the pus cavity. We neither broke up the adhesions nor removed the appendix. A gauze drainage was introduced and dressings applied. The patient recovered and was out and attended to his work. The abdominal wound closed with granulations with a small fistulous opening remaining. A few days after the operation was performed, fecal matter escaped from the wound, showing that there was a perforation.

August 5, Mr. M., the patient, came to me in Hartford, with fecal matter and pus escaping from the fistulous opening in the abdomen. I sent him at once to Watnook Sanitarium where he was properly prepared. I operated on him the next morning. I made an elliptical incision around the cicatricial tissue resulting from the first healing. I found the portion of the abdominal wall thus removed, adherent to the cecum. These adhesions were broken up revealing a perforation in the cecum. This was closed by a double row of Lembert sutures. I then broke up many strong bands of adhesions in search of the appendix, which I finally found and removed. It was in a gangrenous condition, highly infectious. I then closed up the incision, leaving the wick drainage in the lower angle of the incision, which was removed on the second day and the wound closed. Everything went well until the tenth day, when the patient became feverish, with pain near the incision. A small abscess formed external to the superficial fascia, probably from the pus germs which had burrowed in the tissues near the fistulous opening. This discharged and readily healed. At the end of four weeks, patient was up and dressed.

In reviewing this case in the light of all that happened and my experience with many similar cases since, I would say that at the time of the primary operation I should have thoroughly broken up all adhesions, opened and disinfected the multiple pus sacks, which existed, searched and found the appendix and removed it, as no permanent cure could be looked for with this diseased and infectious animal tissue remaining in the abdominal cavity. When at the secondary operation I had found and removed the appendix, broken up the adhesions and thoroughly disinfected the abdominal cavity, I was sure of a permanent recovery. This is what I would advise in all similar cases, although eminent authorities advise to the contrary. There is a theory that the breaking up of the adhesions in pus cases, allows the pus to extravasate and infect the general peritoneal cavity. The fact is, the pus will pass out at the point of the least resistance, which is through the abdominal incision. Frequent irrigation with the use of hydrogen dioxid will render the septic condition aseptic, and a good recovery may be expected.

When the Operation Should be Performed.—In the discussion of this question, the writer will consider it from the standpoint of the best interest and safety of the patient, regardless of whims and sentimental notions.

W. Thornby Stokes, President of the Royal College

of Surgeons in Ireland, says (*British Medical Journal*, July 1, 1895): "As far as I am able to state my opinion on the matter, it is that, if an abscess has formed or perforation taken place, laparotomy should at once be resorted to, but that, short of these misfortunes, operations should be delayed until the last possible moment."

I find in the table of statistics of operations in St. George's Hospital, in London, by T. Holmes (*British Medical Journal*, July 6): Perforation of the Appendix, etc., 10 cases; recoveries 0, deaths 10.

This sums up President Stokes' opinion to mean: That the operation should not be performed at the time when there is a chance of saving the patient's life, but when death is inevitable, with or without operation, then "operate." The worthy president's opinion will insure a large death rate.

Now let us consider a case of a patient with the first attack of infectious appendicitis. He suffers considerable pain for three or four days, and will generally recover from this attack. If you operate, a short incision can be made. You will have no adhesions or complications. The appendix will be found to be slightly swollen and inflamed, but can be readily removed and the stump treated by Dawbarn's method, followed by little if any colic. In nine days he can sit up and in fourteen days go about his work. Now, if you slit open the appendix, you will find an inflamed spot, with probably a few drops of pus and considerable lymph thrown out. Here is the beginning of an interesting and probably an eventful history.

Now, to illustrate, suppose you did not operate. In a few weeks or months he has another attack, severer and longer, resulting in some adhesions. He may go on for two years with repeated attacks, more adhesions form, an invalid condition is well established, gangrene, pus and perforation may have taken place. You then operate under the most unfavorable conditions, with a long convalescence or death. Should not operative measures be an early consideration, rather than the last result?

My statistics covering one hundred cases, are as follows:

Cases without extensive adhesions, infected exudate masses or pus, 27, recoveries 27; cases with extensive adhesions, without infected exudate masses or pus, 25, recoveries 25; cases with infected exudate masses or pus, 23, recoveries 23; cases with infected exudate masses and pus, with perforation and gangrene, 25, recoveries 23, deaths 2; total number of cases, 100, recoveries 98, deaths 2. Males 64, females 36.

In conclusion, the lesson drawn from the proper appreciation of these statistics, contains an important point. We see that in classes first, second and third, no deaths occurred, but in the fourth class are two deaths. As has been stated, this class includes cases with *infected exudate masses and pus, with perforation and gangrene*. Now, with the results of an operation in this class lies the responsibility of the physician and surgeon who knowingly allows the patient to go on to the condition of this class, before an operation was performed.

DISCUSSION.

DR. PARKER, New Orleans—I have listened with much interest to the paper and congratulate the author on his brilliant results. It has been my fortune for the last seven years to be connected with the Charity Hospital of New Orleans where we have about ten thousand admissions annually and about twenty-four thousand at the out-door clinic. I have often wondered why it is that our friends in the North see so many cases of appendicitis and we so few. I do not believe we

have seen half a dozen cases a year. Another peculiarity, they treat a great many negroes, but I have never seen a case of appendicitis in a negro. Dr. Johnson speaks of the catgut suture, but I believe the best suture is an absorbable one. I would like to know how he prepared this catgut. The author mentioned cases of abscess around the appendix and said he did not agree with the opinion expressed that the appendix should not be removed in these cases. In several of my cases, there were abscesses around the appendix and in some cases, the appendix was in the abscess wall. I believe that if we had started in to remove those appendices we would have opened the general peritoneal cavity. Instead of this we opened the abscesses and washed out the region with peroxid, all of the cases getting well and in not one of them has there been a recurrent attack. As to the use of opiates and salines, I believe in the way of preparatory treatment that it is a good plan to open the bowel with an enema and saline. We are all pretty well agreed as to the method of operating, but I do not believe in the use of opium. With regard to fecal fistulae, I have seen several cases. Some of them will heal up by themselves if you let them alone.

THE SECRETARY—The results secured by the author of the paper are almost unparalleled, and such statements coming from a man of such experience and with such good fortune or rather good technique must have a strong impression. Statements read from such a paper would probably be carried away from this section as the authoritative statements of this section and I feel they should be discussed. Another point, that of searching for the appendix in cases of abscess in every instance. I think this matter has been gone into by some of the best authorities. Having been a pupil of old Dr. Henry Parker, who was the pioneer in the advocacy of opening appendiceal abscesses, I saw many abscesses which were undoubtedly what we would have called at that time perityphlitic, and I watched some of these cases for years. I do not remember of a single recurrence of appendicitis after the abscesses were opened and drained. It is a dangerous doctrine to set down any definite technique for any operation, and every case must be judged on its own merits. You might as well say treat all cases of pneumonia with the same drug. The external incision in some cases may be one inch, in others, two inches and sometimes from seven to eight inches, and this must be decided in every individual case according to the requirements of that case. Dr. Dawbarn's recommendation is an excellent one, but there are cases in which it is impracticable to use it. I recently had a case of recurrent appendicitis and I operated during the third attack. I found the appendix as large and hard as my little finger and it was perfectly indurated. The whole lumen of the appendix was destroyed and seemed to be replaced by an enormously indurated wall which was like a hard piece of rigid tube. It was thoroughly impracticable to have cut off that appendix and in such cases we must be guided by the case and not by any definite technique.

DR. CARPENTER, Kentucky—Each case is a law unto itself and must be treated in that way. As to suppurative appendicitis, we can not afford to tear up adhesions and run the risk of opening the peritoneal cavity and poisoning it. If we excise, irrigate and drain; we will save the case as a rule and I think many a patient is lost by meddling surgery. I recently operated on a patient in which the appendix was gangrenous and half sloughed off from the cecum. The cecum was gangrenous for about two inches and the appendix contained an appendolith. I removed this and cut off the gangrenous edges of the cecum. I employed the Lembert suture. I took the meso-appendix and brought it over, drained, irrigated and the patient recovered.

DR. McRAE, Atlanta—I have only had a few cases. One of the points raised by Dr. Parker, I can answer in the affirmative, and that is that I have operated on two cases of appendicitis in the negro, one male and one female. It is true they had a little white blood in them, but they were negroes all the same. They both recovered. I believe that it would be one of the worst theories or practices to state that every appendix should be removed when it is contained in the abscess wall, and I am firmly convinced that it would be a very dangerous practice. I have read the works of many of the English surgeons and the universal experience seems to be that where there is a large abscess cavity with the appendix contained in the walls, simply draining is all that is necessary. It is the exception and not the rule for recurrence to take place. As Dr. Joseph Price has said, when you have a condition of that kind, the time for ideal surgery is not present and you simply wish to conserve the life of the patient. If it becomes necessary to remove the appendix later, I am satisfied that it could be done with less danger than by doing it at one sitting. A large proportion of those cases will die from septic peritonitis. I have had two cases of fecal

fistulae where the abscesses were drained after removal of appendix and one case in which I drained the abscess. If we let them alone, they will get well.

DR. ALEX. HUGH FERGUSON, of Chicago—I can not refrain from commenting on the surgical manner in which Dr. Parker made his remarks. I should like to be excused from discussing the paper as presented to us, but there are a number of points presented which to my mind are not the best procedures and I would like therefore to give a brief outline of how I manage cases myself. I have only had an experience of about 150 cases. I am surprised at the few cases that occur in the South and I think it must be due to the climate. The medical pictures that present themselves to us are, you might say, acute cases, and demand immediate operation. There are some cases which are not so severe, which recover and then have secondary attacks, and then there are others which return after operation when they have simply been drained. I have only had two cases of this myself. They were facsimiles of Dr. McRae's case where the appendix proper was obliterated, but there was a chronic abscess which would become full and cause an attack simulating appendicitis. The most favorable time to operate is between the attacks, and that old surgical rule is good. It is dangerous to operate during the acme of inflammation but sometimes we have to operate at this time, particularly when there is a tumor, otherwise we do not know whether it may or may not burst. The second most favorable time to operate is early, as soon as we have a clear clinical picture of a case of appendicitis, where it is evident that the inflammation is around the appendix. Early operation, say within twenty-four hours, is much more easily done, and the patient is much safer than if you leave it until the fourth or fifth day. The technique of operation varies. An inch and a half and a week and a half is wrong in 99 per cent. of the cases. You may do such an operation between the attacks where the inflammatory process is limited to the inside of the appendix. I once saw a surgeon who was fond of using that old expression, "an inch and a half and a week and a half," who went into the general peritoneal cavity by mistake. The technique of an operation between the attacks is clear. Select your incision and separate the fibers of the muscles. You then expose the appendix that has been inflamed in its quiescent state, and make a circular incision, tying off the mucous membrane, or as I prefer, inverting it by a figure of 8. A simple ligature over the muscular walls is the proper method to my mind. You can not always get your stump in good condition for this treatment but you should drain anyway. If you have to search for the appendix and break down adhesions, it is not necessary to drain. When there is no way of removing the appendix, as in appendicitis fibrosa or where we have much traumatism, capillary drainage is all that is needed. This will drain blood serum but not pus and that point should be looked after. We never aspirate unless the appendix is situated in a region which can be quite easily gotten at. There is no advantage in removing the appendix through the peritoneal cavity, and it is a very difficult way, but it should not be allowed to slough off. When it is in the pelvis, it should not be hunted for. Just as soon as you strike pus, drain it or mop it out. In draining, do so with gauze and with a tube, as gauze will not alone drain pus. The best drain with the gauze is a glass drainage tube, as a rubber one may become clogged up or may be pressed upon by the gas present. I was recently called to the case of a young man who had been riding a bicycle, and a few hours after having been thrown off, he complained of pain in the right iliac region. A physician had been called who diagnosed the case one of appendicitis. I was called about twenty-eight hours later, when the patient had a temperature of 103 and pulse 120. The abdomen was not very much distended but the muscles were rigid. An operation was agreed to and I cut down and removed the appendix, afterward packing with gauze and draining with a glass tube.

DR. HAINES, Omaha I would like to congratulate the author upon his good paper. The first case I had was my most difficult one, and I found extensive adhesions in the right iliac fossa. After a long search I discovered quite a mass, and I felt the appendix within it. My case went the way of all flesh, but I believe if I had had the experience I now have, he would still be in the land of the living. I do not mean to say that it is always necessary to remove the appendix. It has been suggested to treat it as an abscess, which may be a good method. I live in an atmosphere that is impregnated with appendicitis, and we hear of dozens of cases in our local society every time we meet. It occurs in both races. I merely wish to condemn the routine practice of always searching for the appendix.

DR. JOHNSON (in closing the discussion) I expected a discussion and am pleased to have gotten it. Perhaps I hold a

unique position in this operation, as I have been both operator and patient. There is one thing about searching for the appendix. I have done this in the presence of as good surgeons as are here to-day and they have often warned me to discontinue my search. Where you have one large pus sac, you may drain, but almost invariably you will have multiple pus sacs. I find by breaking up the adhesions that you will find you will break into a pus sac just as you may open a wound. I have found as many as five pus sacs in one case, and if you leave these sacs I think they will do harm. Perhaps if some of you will just try the method of breaking up the wall of a pus sac after you have broken up several, you will probably find others near by which will cause, upon rupture, quite a flow of pus. These sacs exist to a large extent, and have been found in the liver and in the whole abdominal cavity. Some patients have died without operation. When the appendix is situated, as it almost always is, in the wall of the pus sac, I remove the appendix. I am aware that you can mention good authority against this procedure, but my experience is that the pus will extravasate into the abdominal cavity and not come out through the incision. From my method I have never had a case of peritonitis resulting, and I think my procedure the proper one. You have a highly septic vegetable matter which it is dangerous to leave behind although I did not think so until I had passed a case where the appendix was removed in a secondary operation. Up to the present time I have had about 125 cases. I think I have seen a great many patients that would not have recovered merely by breaking up the pus sacs. I was sorry to note that Dr. Ferguson did not give any statistics. I would like to ask some of you to try my method. I have tried it although many men have told me not to do it. As to the length of the incision, I think it is often made too long, and a seven-inch incision should not be required in any case. It not only prolongs the operation, but there will certainly be an escape of the small intestines. My experience is that in most complicated cases an incision two or two and a half inches long is enough, and is sufficient to break up adhesions by the sense of touch. A surgeon once saw me operate and remove the appendix, and said he was unable to see or understand how I did it. I think the best way is to enlarge the incision if necessary and that in so doing you are considering the welfare of your patient. When you make a long incision a weakened abdominal wall is the result, and if the patient be a laboring man a strong abdominal wall is of great service to him. Experience soon enables one to perform this operation through a very small incision. If any of you will try this method, you will find that your result will justify you in doing it. The free use of boracic acid and hydrogen will save many cases, and I have been perfectly satisfied with my results. Physicians do wrong in allowing cases to go on before sending for a surgeon. The Dawbarn method can not be performed in every case, but where it can be, I think it should be as there are no infectious points left free in the abdominal cavity. When you first begin to employ this method, you will probably think you will not succeed, but it can be done in five minutes after you get used to it. With regard to fecal fistula, this will usually take care of itself. I remember one case in which the cecum was so far gone that it required a second operation. With regard to the employment of catgut, I buy it in the raw state and sterilize it myself. I first place it in ether and continue to change it until all the fat is taken out of it. I then boil it at a temperature of 173, and then put it away in sterilized glass jars. When I come to operate, I take out the size and quantity I want and again sterilize it. I have so far had no cause to regret its use.

A FEW RECENT CASES BEARING UPON THE QUESTION OF OPERATIVE INTER- FERENCE IN ABDOMINAL AILMENTS.

Read in the Section on Surgery and Anatomy at the Forty-seventh Annual Meeting of the American Medical Association held at Atlanta, Ga., May 5-8, 1896.

BY DONALD MACLEAN, M.D., LL.D.

DETROIT, MICH.

In the following brief paper my main object is of furnish the text for a discussion, by this Section, to one of the most anxious and difficult problems in practical surgery, namely the question of interference or non-interference in cases of abdominal ailment, traumatic or otherwise.

A few recent cases in my practice, together with one or two pathologic specimens, which I wish to present for your consideration, will I trust furnish a reasonable excuse for my occupying a few minutes of the time of this important and busy section of the AMERICAN MEDICAL ASSOCIATION.

So much has been said and written about laparotomy for diagnostic and curative purposes in numerous abdominal conditions that further argument on the subject may seem, to some, to be superfluous. But over and above the great crucial question of operative interference it is generally admitted that individual cases of disease or injury possess a certain amount and degree of scientific and practical interest which entitle them to a respectful hearing and an honorable place in the annals of surgical work. With this view I venture to present the following cases in the hope that at least some inspiration and practical instruction may be obtained from them for the benefit of others both in and out of the ranks of our profession.

Case 1.—Mrs. B. a very obese woman of 50, suffered from absolute obstruction of the bowels for ten days before I was called to see her; stercoraceous vomiting had existed for more than a week, and the patient was in a very advanced state of exhaustion, as may be supposed. The abdomen was tympanitic to the last degree. Temperature 104, pulse 140. The intellect was perfectly clear and by request of her husband and other friends, I explained to the patient herself, the desperate nature of her case and left the question of operation to her. She elected to take the slim chance offered by an operation and I at once proceeded to give the poor woman that chance.

As the result of a somewhat prolonged but most careful examination of the abdominal cavity, I finally succeeded in finding the large egg-shaped calculus which I here present. The intestine both above and below it was constricted so that it constituted a perfect obstruction. It could not be pushed either upward or downward more than one inch in either direction.

I made a small slit through the intestinal wall and removed it, closing up the wound most accurately by the classical suture. No douching was resorted to and the abdominal cavity was closed with all possible rapidity. The patient I regret to say, failed to rally and quietly sank and died in about twelve hours. If I had declined to operate (as I felt greatly inclined to do, owing to the lateness of my opportunity) and if an autopsy had been performed and this calculus found, I should undoubtedly have had serious difficulty with my conscience, one of the things that I greatly fear. Had I seen this patient a week, or a few days, earlier and had I proposed and been permitted an operation then, I can not help thinking, with very deep regret now, that the result would in all probability have been, instead of a melancholy failure, a most gratifying triumph.

Case 2.—C. E., aged 31, consulted me about the end of October, 1895. He gave the history of several well marked attacks of appendicitis, but was apparently quite well and engaged in active manual labor when he came to see me. He complained of a feeling of weakness in the right iliac region and said that he lived in continual dread of something "giving way" in that region. I detected a well marked swelling in the groin and taking the whole case into consideration, I advised an operation which the patient eagerly accepted.

I found the appendix distended with pus. On taking hold of it, which I did with a pair of forceps most gently, it separated from its very slim attachment to the cecum. Fortunately the parts were so thoroughly protected that not a single drop escaped into the peritoneal cavity.

On further investigation very extensive intestinal adhesions were encountered which it took a long and wearisome manipulation to disentangle and it was

found necessary to sew up several large rents in the intestinal walls, each one of which just stopped short of perforation. This patient made a complete and rapid recovery for which we feel sincerely grateful. At the same time it is impossible to evade the reflection that an earlier operation would have proved much easier for the surgeon as well as vastly safer for the patient.

This case may in all fairness be taken as a representative of a considerable number which have occurred in recent times in my practice.

Case 3.—F. J., aged 19, consulted me on February 15, in regard to repeated attacks of appendicitis, only one of which had been severe, and that was more than a year ago. He presented the appearance of a perfectly healthy and vigorous young man, six feet high and weighing 170 pounds. I advised postponement of operative interference on account of his apparently perfect health. Next day, however, he returned in a very different condition, tongue furred, pulse 120, temperature 101. I had no choice but to change absolutely my view of his case and urge an immediate operation. As he was an only child and a young man of unusual promise, the responsibility was proportionately heavy. My advice was accepted and the operation performed. The appendix was found deeply imbedded in an immense inflammatory mass which surrounded the cecum and made the operation a most difficult and anxious procedure.

The testimony of this case could not be mistaken, that longer delay would have insured ever increasing danger to the patient, while an earlier operation would have been comparatively easy for the surgeon and much safer for the patient.

The following case is recorded here partly on account of its furnishing an additional argument in favor of early operation in *suitable* cases and partly on account of the very unusual and interesting complications which resulted from postponement of operative interference.

Case 4.—V. P., aged 40, a very powerful man, a blacksmith by trade, was taken suddenly and violently ill with all the characteristic signs and symptoms of appendicitis, including well marked swelling in the usual situation. He was attended by his regular medical adviser, who lived near him in the country. On the occasion of my first visit I found the patient in very great distress from constant cough with excessive expectoration of an indescribably fetid character. He had high temperature, rapid pulse, total loss of appetite, with proportionate general weakness. The swelling had entirely disappeared from the region of the appendix and he complained of pretty severe diarrhea. With all possible expedition I had him transferred from his home in the country to Harper Hospital in Detroit.

I suspected that an appendicitic abscess had burrowed behind the peritoneum and invaded the right lung, in short that nature was making an uphill struggle to get rid of the pus through the bronchial tubes. On this theory I ventured to make an incision between the sixth and seventh ribs on the right side and had the good fortune to tap at once the depot of fetid pus. Without resecting a rib I introduced the nozzle of the douche and washed out the abscess cavity thoroughly, with the greatest relief to the patient, whose condition immediately began to improve. The douching was repeated twice daily for about two weeks when all discharge having ceased, the drain tube was removed and the opening permitted to close. Three years have elapsed since this patient passed from my care, but I have met him quite recently, the very picture of manly health and vigor.

Case 5.—J. Y. C., aged 35, riding bicycle between 5 and 6 P. M. Saturday, April 26, suddenly found himself in most dangerous proximity to an electric car. In his desperate effort to avoid the collision with the car, he unfortunately fell from his wheel and alighted on the asphalt pavement with very great force on his buttocks. He got up, however, and mounted his wheel and rode some distance. He then partook of a very liberal meal, after which he went in the company of a young lady friend to a pub-

lic entertainment, after which he accompanied her to her home. After parting with his young lady friend he started to go to his own home, but on the way was taken so ill that he stopped at a drug store and telephoned for my assistant, Dr. F. B. Tibbals, who at once responded and on hearing the history as stated above, administered an anodyne and accompanied the patient to his home and saw him comfortably to bed.

During the next day alarming symptoms very gradually developed and in the evening I was asked to see him. I found him very tympanitic, face pinched and pale, pulse 120, temperature 102. Arrangements were instantly inaugurated for a laparotomy and the operation was performed at 10 p.m. It was a serious undertaking. The bowels distended to their utmost capacity with gas, the abdominal muscles tense and unyielding, the history and symptoms absolutely vague and indefinite. The patient and his family were candidly informed as to the essential danger and uncertainty of the case, but all were anxious that an operation should be performed. I have here, the specimen which explains the whole case, which in brief was this: An ancient ulcer of the stomach had induced a firm adhesion between the pyloric end of the stomach and the duodenal mesentery. The jar of the fall had had the effect of separating this adhesion and thereby caused a rupture of the stomach at the point of the ancient ulcer and consequent adhesion. I carefully stitched this rupture and with gallons of sterilized hot water washed from the peritoneal cavity all the foreign matters which had escaped from the stomach, after which I closed the abdominal incision. The whole procedure was conducted with the utmost possible expedition and during its performance every means of stimulation were resorted to, hypodermically and otherwise.

For some hours we had reason to hope that our forlorn hope might be crowned with success, but in spite of all effort the patient gradually sank and died about twenty hours after the operation. The case is a peculiar one from every point of view, and in my opinion serves to illustrate the value of early exploration and operation in cases of abdominal traumatism. More especially does this case serve to show the importance of careful examination and the value of the most trivial and apparently unimportant symptoms following an injury which, in its essential nature, ought to excite suspicion.

It seems proper to state here that in addition to the morbid condition of the stomach already described and which the specimen fully demonstrates, we also found an uncommon congenital condition. The left kidney was situated just below the promontory of the sacrum and was very small and very imperfectly developed. That this abnormality may have had some part in the fatal issue is in my opinion reasonable to suppose. At any rate it is a fact that complete suppression of urine existed from the time of the accident to the end of the patient's life.

DISCUSSION.

DR. THOS. H. MANLEY, New York—I recently had a case that in some particulars was so much like Dr. MacLean's that I would like to mention it. I must take exception to some things generally considered important in reference to making an early incision. There are some cases I think of which an early laparotomy will throw but little if any light. The case I refer to was that of a young man who had been kicked by a horse. At the time of the accident he was pressed against the sharp edge of a feed pan. The shock was very great, and although he was able to raise himself, he only walked a short distance before collapsing. His family physician found him in a state of profound shock, perfectly rational but cold. By active measures reaction was brought about in twenty-four hours, during which time the patient did not pass a drop of urine. Shortly after the establishment of reaction vomiting commenced and an unquenchable thirst set in. I was sent for and made a careful examination of the case. As a result of auscultation of the abdomen and a very thorough examination I found evidence of internal hemorrhage. One would suppose that we should have had renal hemorrhage and not peritoneal. I ventured the diagnosis of laceration of the ileum. There was some intestinal trouble but I found evidence of intestinal peristalsis through the entire tract. I believed the peritonitis was due to the blood. Marked tympanites was present which subsided under treatment. On the fourth day, after everything seemed

very encouraging, bad symptoms set in, the most serious of which was fecal vomiting. After placing the matter thoroughly before the family and warning them of the dangers and how little good could be promised, we opened the abdomen; the first thing I did was to go for the kidney on the right side but there was no kidney there. I then pressed my finger along the groin but there was no kidney there and I then thought of the horse shoe kidney. I found it lying over the cecum, and it was very large. I lifted up the bowel and about five feet from the duodenum I found two large gangrenous patches, one of which had just perforated. I was never more satisfied with the ease of an operation than I was in this case. My patient sank and died. Now the point is this. Suppose a laparotomy had been done immediately after the accident, what good would it have done? This point suggested itself to me particularly with reference to the displacement of the kidney. I have seen only two cases in my life of this curious and unusual state. It was a very interesting case and it taught me a great lesson. In these cases we must be guided by general principles and not by established lines.

THE PRESIDENT asked if the patient died in twelve hours from hemorrhage or from shock.

DR. MACLEAN said he did not think it was from hemorrhage. The gallstone was removed from the jejunum.

THE PRESIDENT—The *British Medical Journal* recently contained a report of a case of the removal of a stone about the size of the one removed in Dr. MacLean's case and the patient died on the third day from hemorrhage. I removed a stone larger than this about four months ago, the stone weighing 300 grains, and the patient died on the third day of hemorrhage.

DR. J. T. THOMAS, Pennsylvania—I rise to bring up the question of enteroliths, which is supposed to be a very simple matter. I would like to have the experience of the gentlemen present with regard to the result of these cases. A few years ago I saw a patient suffering with an obstruction resulting in fecal vomiting. Operation was declined until he was in *extremis*. On opening the abdomen and examining this obstruction an enterolith was found about the length of the one presented here, which entirely occluded the lumen of the intestine. It would be a very simple matter to remove an enterolith by incision. In this case the patient never rallied and he died in about two hours. From the case reported by the doctor and from my own case, I suspect that these cases are more fatal than is generally supposed.

DR. WINSLOW, Baltimore—As long as the gentleman who has just spoken has put a case before the meeting and as long as the result of these cases appears to be fatal, I would like to add my contribution of an equally fatal case of a similar nature. I was called a few years ago to a lady who had presented for three days symptoms of obstruction of the bowels. She had no very great pain, but had vomiting and persistent constipation, notwithstanding the administration of various remedies. The patient was 65 years of age and very fat. The abdomen was not very tympanitic, and the symptoms were those of intestinal obstruction. I proposed operation, which after some consideration was accepted. On opening the abdomen, to my surprise, complete intestinal obstruction was revealed, due to an object within the bowel. I had anticipated that the obstruction was due to a twist in the bowel, or perhaps to some malignant trouble which I could not feel through the abdomen. On making an opening, the mass proved to be a gallstone of about the size of the one referred to by Dr. MacLean. The woman died shortly after the operation. This brings me to a point which is perhaps well known, but which nevertheless can not be emphasized too often. In the vast majority of cases of symptoms of obstruction to the bowel it is impossible to know before opening the abdomen what is the nature of the mass within. Personally I find, in a large number of cases, that the condition present upon operation is very different from what you would imagine previous to the operation. I will mention another case which occurred two or three years ago. It was only possible to get a very meager history, as the man was a foreigner and could not speak English. He seemed to have been injured by the pressure of a car, and he complained of considerable pain in the abdomen and some vomiting. There were no other symptoms. After seeing him I left town and the following day was telegraphed for to return and operate on him. I found him in a bad condition and the symptoms already suggested peritonitis. There was no time lost in opening the abdomen, when the condition found was perhaps familiar to most of you, but was very interesting to me. It was very difficult to find the trouble, but after searching his abdomen and removing a large portion of the intestinal tract, I discovered a genuine hernia in a sac which was entirely within the peritoneal cavity. On lifting the intestine the bowel appeared to point into a sac behind the pubic bone, and this portion of the bowel

was entirely gangrenous. It is needless to say that he was beyond hope and that he could only live a day or so. The point was my surprise at the condition which I found upon opening the abdomen. The man who performed the postmortem over-looked the sac and I again examined the body to verify its existence. There was a distinct pouch which could contain six ounces of fluid. Other cases have come under my notice in which the condition found was very different from what had been expected, and it is well to emphasize that we can not tell what the pathologic condition will be until we have opened the abdomen.

DR. PHILIP MARVEL, Atlantic City—I wish to report a case which will be of interest from a surgical standpoint because of what did not exist. About six months ago I was summoned to see a lady who had fallen in a store, and who for ten hours had seemed to be in hysterical convulsions, which had recurred at intervals of about half an hour. Total suppression of urine existed from the time she was brought to me. Autopsy showed but one kidney, which was on the right side in the normal position. Examination showed a movable capsule and macroscopic and microscopic examination showed it was not diseased. From the time the lady was taken, when she was in perfect health, until the time of death, she was in a semi-conscious condition.

DR. McRAE, Atlanta—I would like to mention one case in this connection which has been of great interest to me and which I have reported once before. I report it because of its extreme rarity and its medico-legal interest. The condition was due to a stab received between the sixth and seventh ribs six months prior to the time I saw the patient. When I saw him he had been suffering with intestinal obstruction for three days. The diagnosis made by the physician who was first called in attendance was that of cramp colic and he administered morphin. On the third day a consultation was held and it was thought that the patient had a hernia of the diaphragm. The physician who had attended the man when he was first injured was then called in and he confirmed the diagnosis. I was telegraphed for to operate, and when I saw the man at nine in the evening he was in an extremely bad condition. He had a rapid pulse, a pinched expression and other symptoms. I stated the case very clearly to the physicians as well as to the gentleman himself, and I think the man really desired an operation because of its medico-legal interest, as he felt that he had been the subject of an unprovoked assault. He also felt that he was entitled to the bare chance that an operation would give him, but he desired to make his will, so the operation was postponed until next morning. Considering the condition in which I found him I think the Association will consider that it was not with a great deal of assurance that I went into the abdomen. I did so with much hesitation, as I believe up to that time no cases of operation for hernia of the diaphragm had been reported. There was an opening in the diaphragm, with a band of adhesive tissue extending up to the exact point where the stab wound was. At the point of the scar there was a tumor and it was impossible to draw the intestine down. It was clear that the man would die, and I felt justified in proceeding with an investigation of the case. I enlarged the opening in the diaphragm until I could put my hand into the left thoracic cavity. I found a portion of the small intestine in the pleural cavity and the lung was compressed. I kept on until I had removed the hernia. The adhesions were very dense. The condition of the bowel was one of beginning gangrene. The patient came out of the anesthesia and died about 5 o'clock. The interesting feature was the same as that mentioned by Dr. Ferguson. I placed my hands around the heart, which would continue to beat immediately upon being released. Another interesting point was my position on the stand. The man who did the cutting was declared not guilty.

DR. MACLEAN, in closing the discussion—If the result of my paper and the discussion is summed up in a single sentence, it is that the surgeon should have the courage of his conviction and should go boldly and honestly and sincerely before his patient and the friends and advocate an early exploratory operation. My case was lost for the want of early operation, and the same is true of all the cases of which we have heard to-night. The chances are reduced to a minimum by delay. I have this to say as my belief, and I am sure it will command the approval of others, that we should not hesitate or shrink from advocating an exploratory operation in all doubtful cases of abdominal trouble. Some of these cases get well of themselves, but for every one that does, ninety-nine do not. The object of my paper, and I think the lesson taught by this discussion is, that when we are brought face to face with an abdominal injury or an acute attack of abdominal inflammation, we should lay down the law with a degree of confidence that will convince our patient that operation is the right and only thing to do. If in

my paper and in this discussion this lesson is impressed upon the members of this Section, I certainly shall feel that any little trouble to which I have been put has been repaid a thousand fold.

REPORT OF CASES ILLUSTRATING THE ADVANTAGES OF A NEW AND ORIGINAL METHOD OF OBTAINING MATERIAL FOR SKIN-GRAFTING.

Read in the Section on Surgery and Anatomy at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY Z. J. LUSK, M.D.

WARSAW, N. Y.

At the meeting of the New York State Medical Association on October 17, 1895, I read a paper describing a "new and original method of obtaining material for skin-grafting," reporting two cases in which it had been successfully employed.

The paper was subsequently published in the *Medical Record* Dec. 7, 1895, Vol. 48, page 800. It was illustrated with three cuts of Case I, showing his condition nine months after over 800 square inches of raw granulating surface had been healed. The accident which deprived this large surface of its integument occurred on Jan. 14, 1895, and was caused by patient falling into a pan of boiling brine at the salt works. His injuries were so severe and shock so profound that I did not think it possible for him to long survive. He rallied, however, and negatived my prognosis from day to day for four weeks, when I began to think the fellow had a possible chance of recovery.

I quote briefly from the paper published: "He was in a condition of extreme emaciation, with nearly one-fourth of the surface of the body in a raw granulating condition. Skin-grafting became necessary, and I was at a loss to know where material could be obtained sufficient to heal this enormous surface. No one could be found willing to contribute strips of skin required in the Thiersch method, and certainly none could be obtained from patient. Meantime, while reviewing the various methods employed in skin-grafting, an idea occurred to me, suggested by the numerous patches of exfoliated epithelium, the result of vesication; they were hard, dry and crisp, having been separated from the cutis now nearly five weeks. Believing that this material could be utilized, on February 16, in the presence of attendants and others, I did skin-grafting, using a patch of this dried epidermis adhering by one edge to dorsal surface of right foot. A piece about one inch square was softened and sterilized in a warm boric acid solution, and divided into twelve grafts which were applied to the anterior granulating surface of left thigh. The result was eminently satisfactory. Seven of the twelve grafts took nicely, developing into vigorous islands of skin. The subsequent treatment consisted in the use of this dried epithelial tissue, with which these large surfaces were covered with substantial skin by April 1. At the spring meeting of the Wyoming County Medical Association, Dr. Roswell Park, of Buffalo, New York, who was present as our guest, complimented me on my discovery, commenting particularly upon the integrity and firmness of the skin, the perfect use of joints, and the entire absence of cicatricial contraction."

At this meeting I expressed the opinion that epidermis raised by cantharides could be successfully

employed in skin-grafting. An opportunity of verifying this statement occurred three months later, when I successfully healed a large varicose ulcer of eight years' standing with grafts raised by vesication with cantharides. Since reporting my experience in October, 1895, I have done skin-grafting on the following cases:

Case 1.—M. C., Irishman, twenty-three years of age, salt-lifter at Empire Salt works, slipped into a pan of boiling brine Dec. 23, 1895, severely scalding both legs, large blisters filled with coagulated serum covered dorsal surface of both feet. The epidermis on both legs was torn, hanging in shreds, with blood oozing from calf of left leg. Sloughing took place later, leaving a raw granulating surface five inches long by three wide, two inches above internal malleolus of left leg.

December 23 I did skin-grafting, using a patch of dried skin adhering by one edge to dorsal surface of right foot. The granulations were first thoroughly irrigated with warm sublimated solution followed with normal saline solution. The patch of epithelium was softened in warm solution of boric acid, and placed conveniently for cutting grafts. With a pair of common artery forceps, the skin was caught up at one corner and a narrow strip from one to two inches in length cut off and held with the free end resting at a point where a graft is to be applied. A piece about one-twelfth inch square is clipped off and carefully pressed into granulation; then it is moved from three-fourths to one inch where another graft is applied, and so on until a suitable number have been planted. A layer of sterilized gauze, saturated with a mixture composed of balsam of Peru and castor oil, in the proportion of one dram to the ounce, is applied over grafted surface, and over this three or four layers of sterilized cotton, which are held in place with strips of adhesive plaster and finally covered with a roller bandage.

In three or four days the condition of things can be easily ascertained by separating the cotton covering, which can be done without disturbing grafts. In this case dressings were not changed until the fourteenth day. A majority of the grafts had taken nicely, and on January 24 the surface was completely healed and he was up and about. On December 26, the date skin-grafting was done, I removed several patches of the dried epithelium, placed them between thin layers of borated cotton, tucked them into an envelope and laid them away in a drawer in my office desk to be tried on my next case of skin-grafting.

Case 2. On January 7, I was called to attend F. H., German; while chopping wood, December 24, with a double bitted ax, it became set in the log, and in his efforts to liberate it, it flew out, striking the dorsal surface of right foot over tarso-metatarsal articulation, cutting a gash two and a half inches wide, paring off the skin for about two inches. Two weeks later, when I was called to see him, his foot was swollen with a surface two and a half inches wide by two inches long, covered with unhealthy granulations.

They were curetted and treated antiseptically, and on January 12, 1896, I did skin-grafting, using a patch of the dried epidermis taken from Case 1, as described. Twelve grafts were applied. Ten days later, when dressings were changed, six of the grafts had taken nicely. At the next dressing two more appeared, making eight in all. The discharges had ceased altogether, and ten days later the wound was thoroughly healed.

Case 3.—Mrs. B., 48 years of age, cancer of left breast. I operated for its removal Jan. 26, 1896, leaving wound open except in axilla. February 3, there was a healthy granulating surface five and a half inches long by three wide in the center. A patch of cuticle was raised using for the first time a blister

plaster called canthos, which is superior to anything of the kind I have tried, producing vesication in from one to three hours. In this case less than three hours sufficed to raise a blister three inches long by two wide, two inches from ant. sup. spinous process.

Care is necessary in removing the blistered cuticle, otherwise it may become wrinkled and ragged, being easily torn, making it difficult to determine the proper surface to be applied. It is easily removed after separating by carefully clipping around the edges; then covering with moist, sterilized gauze, when it is caught up by two edges, cuticle and gauze, and turned over so that its distal or outer surface rests on the gauze. The proximal surface is covered with the same material, the whole secured at each end by pins and placed in sterilized boric acid solution; after moisture is absorbed with sterilized cotton it is placed where grafts can be conveniently cut. The technique followed is the same as that employed in previous cases. About forty grafts were applied, a majority of which took nicely, and on March 6 this surface was healed with a covering of substantial skin.

Since the publication of my paper in December, 1895, clinical reports of the successful use of epidermis raised with cantharides have been published as follows: Dr. Leonard Freeman, of Denver, Col., (late Prof. of Surgery in the Woman's Medical College of Cincinnati), in a letter published in the *Medical Record* Jan. 25, 1896, claims to have done skin-grafting, using epidermis cut from a cantharides blister. His case was an aged darkey with an old crural ulcer, "probably syphilitic." He cut a plaster of appropriate size and left it on the man's thigh over night, when it was separated and transferred to the ulcer, on the surface of a pad of gauze. An attempt had been made to sterilize the ulcer with bichlorid compresses. He states that some suppuration occurred about the margins, but much to his surprise the graft "took nicely."

In a letter dated April 4, published in the same journal, page 499, Dr. Frank Overton of Patchogue, New York (late surgeon of the City Hospital, New York), describes his experience as follows: Just above the angle of the jaw of a nervous girl, 17 years of age, there was an ulcer two inches in diameter, the result of curetting a wen Jan. 3, 1896. On January 10, granulations looked perfectly healthy, when a blister was raised by cantharides and two grafts applied, each the size of a thumb nail to the anterior part of the wound. Iodoform gauze dressing was applied to the wound. "On the 16th this was removed and with it one of the grafts. Another of the same size was raised and applied. On the 24th the area of the first graft seemed to be covered with epithelium, but thin. On the same day the lower part of the wound was grafted according to the Reverdin method, with four or five pieces of skin taken from the mother. On January 29, both the areas of blistered grafts looked healthy, and had nearly covered the ulcer, but those from the mother were growing far more rapidly than those from the blister."

Dr. Robert T. Morris of New York City, in his book just published on, "Appendicitis with Notes on other Subjects," has on page 151, a note headed "Skin-grafting from Blisters," in which he says: "Skin-grafts for application according to the method of Thiersch may be obtained from blisters;" that the idea of using grafts of this sort first occurred to him while treating burns in which large blebs had

formed. After securing and cleansing the separated cuticle in physiologic saline solution, it was replaced upon the sterilized wound where it adhered well. That since that time he had obtained blister grafts with cantharides and had successfully applied them to small wounds.

Just when the idea first occurred to the author or how long he has been doing skin-grafting by this method, is not stated. In his preface he mentions a list of periodicals in which he says, that the substance of many of the notes have appeared. Among the number mentioned I can find no reference to skin-grafting with blisters, hence I conclude that the first publication of his experience is that which appears in his book just published, 1896. It will be observed that in all cases reported, grafts of large size were used. In that of Dr. Freeman, cantharides was applied of appropriate size and allowed to remain until the following morning, when it was transferred directly to a septic surface and under these conditions "took nicely."

In Dr. Overton's case grafts no less than one-half, probably three-fourths inch square, were applied. Six days later one was removed with dressings when another of same size was applied, and finally developed into a healthy covering, by February first, twenty-one days after first graft was applied and fifteen days after second.

My experience with large grafts was invariably attended with negative results. With careful attention to asepsis, little septic blebs would lift the grafts in places, so that in changing dressings, if not removed, little evidence of life could be seen. Very often they will become disintegrated and disappear in the secretions. If on the eighth or tenth day pus is not materially lessened in quantity, you may be pretty sure that your grafts are a failure. On the contrary, if the secretions are materially augmented, you may be satisfied that grafts have taken and are doing well. Grafts not larger than one-twelfth inch square when properly applied nearly always take nicely. On the tenth or twelfth day the grafted surface will be studded with numerous depressions surrounded with atrophied granulations and from this time their growth is surprisingly rapid. The epidermis raised with cantharides is less porous than that separated by the knife according to the Thiersch method. I am convinced that the method of applying dressings, permitting frequent examinations without disturbing proximal covering and the application of the aseptic mixture is followed with better results on granulating surfaces than the so-called dry dressings.

Various experiments have been made to ascertain the limit of vitality of grafts separated from the body. The longest period of which I can find any record is ninety-six hours.¹ In my first case, I successfully healed a granulating surface three and one-half inches in diameter with grafts which had been separated from the body forty-eight days. In the case reported by Dr. Freeman, the cantharides plaster was attached to the cuticle from twelve to fourteen hours, which demonstrates one important fact in connection with the cuticular epithelium and that is, that it will undergo any treatment short of total annihilation and yet, when returned to its natural environment, it will become revitalized and awakened into new life and activity.

What are the advantages of this method as compared with those generally employed? 1. By the Thiersch method the operation by which material is obtained is exceedingly painful, so much so that in cases weakened by their injuries and especially in children, the surgeon has to seek kind and obliging friends of his patients in order to obtain the necessary grafts. Such friends, as a rule, are very scarce under these circumstances. 2. The technique requires the skilled operator to properly cut or shave off the grafts. There is also the danger of transmitting syphilis or other infectious diseases. The same objection would apply to the Reverdin method, though to a less degree, being less painful.

By the method which I have described, the advantages are: 1. The material for grafting can be obtained from the patient *per se*, without causing pain or discomfort, with the danger of transmitting syphilis or other diseases eliminated. 2. The technique is simple. A surgeon or general practitioner with a knowledge of antiseptics and ordinary surgical skill can successfully operate. 3. It is quite as potent in healing wounds of large size more rapidly and with results as perfect as by any method known, the skin produced being soft and pliable with no keloidal cords and in many places so natural that it can scarcely be distinguished from normal skin.

A SAFE METHOD BY WHICH ANESTHETICS MAY BE ADMINISTERED WITH OXYGEN.

Read in the Section on Surgery and Anatomy, at the Forty-seventh Annual Meeting of the American Medical Association at Atlanta, Georgia, May 5-8, 1896.

BY J. N. DEHART, M.D.

BROOKLYN, N. Y.

Since the discovery of the application of ether by Dr. Morton, of Boston, and its first use in the Massachusetts General Hospital by the late Dr. J. C. Warren as an anesthetic in 1846, there has been a great desire that some means should be devised by which all danger might be allayed, so that the patient could not be rendered cyanotic, especially when there was disease of the heart or kidneys that complicated the patient's condition. While ether has had the preference to chloroform in our country, yet in Europe the latter has been more universally used, and at the present day is also being adopted for anesthetic purposes in many private sanitariums, either alone or in the A. C. E. mixture.

Among the advantages derived from the use of chloroform are that it requires a much smaller amount to produce anesthesia, the patient becomes unconscious more rapidly and there is less bronchial irritation and excitability, there is a more prompt return to consciousness and hence less unpleasant effects afterward; all of which are worthy of consideration, and with care on the part of the person administering the anesthetic would tend to lessen the mortality in such cases where chloroform was used.

Since the early part of last year many surgeons in various cities of the United States have been devising means by which anesthetics could be given with oxygen gas during surgical operations. The most important factor in this mode of giving them was a properly constructed inhaler, by which the patient could breathe the anesthetic with oxygen gas and at the same time expire the carbonic acid gas; the latter would often cause cyanosis and also nausea when given in the usual way with a cone.

¹ Georges Martin, Encyclopedia of Surgery, Vol. I, p. 543.

Having observed the giving of anesthetics with oxygen in a few cases during an extensive tour of the Northwest and South last spring and summer, and my attention having been called to the need of a properly constructed inhaler for this purpose, in December last at the request of several surgeons to whom I had related what I had already observed, and they having expressed a desire to give oxygen gas a fair trial with anesthetics, I visited several surgical instrument establishments and after carefully examining the various inhalers in them, I saw what seemed to me would make a practical one, and began devising designs for this purpose. I think that I have had constructed such an inhaler, which has been used in over one hundred cases in the various hospitals of Brooklyn, New York city, Boston and vicinity by myself, and I can safely say that it has been used since Jan. 1, 1896, over five hundred times by the surgeons of these hospitals, and also in the private hospitals and practice of many others.

The illustration which accompanies this paper shows the inhaler adjusted for immediate use. It consists of a nickel-plated mask with a rubber face guard and valve for expired air. This valve is made of two metal discs, between which is placed a rubber disc. These are enclosed in a nickel-plated box with

a movable cover and slot for expired air. This mask is connected with a graduated bottle with metal cap and two nickel-plated tubes. The long one contains two small brass nebulizing tubes, so that the anesthetic is carried over to the patient as a fine vapor. This bottle is connected with the cylinder containing the oxygen, which supplies the pressure and should be allowed to flow slowly into the bottle. Another mask made of vulcanized rubber with nickel-plated frame and nickel-plated box, containing a metal disc, secured by a movable pin, and underneath it having a rubber disc for expired air, is also made. This mask is connected with a larger graduated bottle and two hard-rubber tubes, the long one having two platinum points for nebulizing the anesthetics. This bottle is also connected with the cylinder containing the oxygen gas. A double air bulb can be used with either of the masks and bottles, when the oxygen gas gives out during a surgical operation, or if it can not be obtained in cases of emergency.

At the suggestion of a prominent surgeon I made a small box and attached it to the rubber mask and placed a sponge in it on which ether, chloroform or A. C. E. mixture can be dropped and rapid etherization produced in minor surgical operations and obstetric cases.

The advantages derived from using anesthetics with oxygen gas are:

1. That there is seldom or never any period of excitement during the early administration of the anesthetic.

2. There is no nausea nor vomiting nor cyanosis at any time while giving the anesthetic, either in the early stage or during the operation, except in cases where brandy may have been given for a stimulant either before or during the operation.

3. The patients are more readily restored to consciousness than when anesthetics are given alone and make a more rapid recovery.

4. A much smaller amount of the anesthetic is used, usually about one-third the quantity, and seldom more than three or three and one-half ounces of ether per hour and the same proportion of chloroform or A. C. E. mixture.

Through the courtesy of several surgeons in Boston, New York, Brooklyn, Albany and other suburban cities I am enabled to report a few of the more interesting cases where my inhaler was used with anesthetics combined with oxygen gas.

Case 1.—F., aged 40, Dr. Charles McBurney, Roosevelt Hospital; carcinoma of left breast. Ether with oxygen gas (dilute). Patient came under the anesthetic very slowly and was removed to the operating room in a few minutes after etherization was commenced. A small nodule about the size of a walnut was found just below the nipple in left breast, which had been developing for some months past, and recently had become quite painful on pressure and at times sharp pains radiated from it in different directions. Have no knowledge of any hereditary taint in any members of her family, either on father's or mother's side. This was dissected out and wound dressed antiseptically in thirty-five minutes. Two and a half ounces of ether was used and about ten gallons of oxygen (dilute). There was no nausea nor cyanosis during the entire operation, and patient recovered consciousness soon after leaving the operating room.

Case 2.—F., aged 35; Dr. G. R. Fowler, Brooklyn Hospital; carcinoma of right breast. No family history was obtained at the time of the operation nor afterward. Ether with oxygen (dilute) was given to the patient and she came under its influence in seven minutes without any nausea or cyanosis or excitement, passing from first to second stage and then to complete anesthesia. The entire breast was removed, as the carcinoma involved almost the whole glandular structure and would soon have broken down. There was very slight hemorrhage and but few vessels were ligated. Afterward the pectoral major muscle was also dissected off, as it was thought best to do so, lest the carcinoma had also affected a portion of it. The axillary glands were also removed. The wounds were then dressed antiseptically and catgut sutures were used to approximate the edges of the wound, and iodoform gauze and bandages were applied to the chest.

No nausea, no vomiting nor cyanosis during entire operation, which lasted one hour. Four ounces of ether and twenty gallons of oxygen (dilute) were used. Patient became conscious before leaving operating room.

Case 3.—F., aged 32; Dr. Picher-Sengc, Memorial Hospital, Brooklyn, N. Y., section of trifacial nerve. This patient has had a persistent neuralgia for a long time past and been under the care of several surgeons, who could not afford much relief by any medical treatment short of a surgical operation, which she finally consented to have performed. Had an exploratory operation a few days since, in which an incision was made through the integument covering cheek and eyelids, about two and one-half inches in length, and closed with adhesive straps until to-day, when it was opened and continued underneath the superior maxillary bone. Chloroform with oxygen (dilute) was given and patient yielded to its anesthetic effect in three and one-half minutes. No excitability, nausea nor vomiting or cyanosis during the entire operation, which lasted one hour and fifteen minutes and consumed one ounce chloroform and fifteen gallons oxygen.

Case 4.—M., aged 68, Hebrew: Dr. G. R. Fowler, Brooklyn Hospital; supra-pubic cystotomy. Chloroform with atmospheric air was given by means of a double air bulb, the supply of oxygen (dilute) which the hospital always keeps on hand, having been exhausted by two cases of asphyxia from illuminating gas which came in during the previous night. Patient came under the anesthetic effect of the chloroform very readily

in four minutes without any excitement, nausea or vomiting, and passed rapidly to an unconscious condition. An incision two and one-half inches long was made along the median line and above the pubic region. A careful dissection through the abdominal wall exposed the bladder to view, a sound having been previously introduced into the bladder and held by an assistant, an incision was made through the parietes of the bladder and a careful exploration made of its contents. An encephaloid was found and a mass that would fill a dessert spoon removed with a curette, after introducing it several times. The bladder was then carefully washed out with antiseptics and incised wound closed with sutures. There was very little hemorrhage during the operation. Iodoform gauze and bandages were applied and patient removed from operating table to his room, when consciousness was restored. There was no cyanosis nor vomiting during the operation, which occupied forty-five minutes, and three ounces of chloroform were consumed. The pulse, temperature and respiration were normal during the entire operation, a gum elastic catheter (large size) was passed through an incision made in the perineum and upward into the bladder and secured there for drainage.

Case 5.—M., aged 48; Dr. McDonald, Albany Hospital, N. Y.; ankylosis of left knee-joint with bad union of fracture. Was kicked by a horse some time since and had acute synovitis, followed by this deformity of the limb. A. C. E. mixture was given with oxygen. Patient came under its anesthetic influence in four minutes and passed from first to second stage without any excitement or nausea. Partial resection was made of upper end of tibia. Adhesions were loosened and bone broken over again as near former fracture as possible, so that there was good motion of the joint obtained, which would enable the patient on recovery to walk with only a slight limping gait. The limb was then flexed and dressed with plaster paris bandages and an angular wooden splint secured underneath the knee-joint. Pulse and respiration good through entire operation, which occupied one hour. Esmarch bandage was first applied to aid in controlling any hemorrhage, and it was very slight, during the operation only a few ligatures being required.

Case 6.—F., aged 24; Dr. A. Vandereed, Albany Hospital; necrosis of nearly two-thirds of right femur, with ankylosis and distortion of knee-joint. Ether with oxygen (pure) was given and patient yielded to its influence in five minutes, passing rapidly to an unconscious condition. Esmarch bandage was first applied to control hemorrhage, and amputation of limb was made at upper third of femur by a flap operation. After ligating blood vessels and washing the stump antiseptically it was found necessary to remove another inch of the femur, as it was found to be necrosed farther up than the external appearance of the limb would indicate. Pulse and respiration normal during the entire operation, which lasted fifty minutes. There was no nausea, vomiting nor cyanosis at any time. Glass drainage tube was inserted.

Case 7.—F., aged 40, weight 121 pounds; Dr. Kittredge, of Nashua, N. H., was the family physician. Dr. Irish, of Lowell, performed operation for resection of ribs on right side. Patient had an attack of pleuro-pneumonia, followed by effusion in the chest. The usual remedies had been tried but failed to absorb the fluid. The failing health of the patient, with symptoms of pyemia necessitated resection of ribs on right side in order to get good drainage. A. C. E. mixture with oxygen (dilute) was given and patient yielded rather slowly to its effects. There was no nausea or cyanosis and patient passed to an unconscious state in ten minutes, showing how non-susceptible some are to the anesthetics, no matter which are used. After removing a section of rib and enlarging the opening, there was a very abundant flow of very foul-smelling and flocculent fluid to the amount of twelve or fourteen ounces. A drainage tube was inserted after the cavity had been thoroughly washed with a solution of salt and water, and afterward with a weak solution of peroxid of hydrogen. Patient has improved, for the past week in good health, and there is continued flow of fluid through drainage tube, but does not have such a bad odor as formerly.

Case 8.—F., aged 35, laparotomy; Dr. Wm. M. Conant, Boston, Mass. This patient has had pain in right side and also in lumbar region of same side for some months past. There has been some swelling and tenderness on pressure recently in same locality. Has not made the usual quantity of urine for several weeks past and there has been partial suppression at times, which necessitated catheterization. A careful diagnosis led to the belief that the kidney was involved and also the right ovary. Ether was given alone at first and on my arrival the vomiting was so persistent and the operation had been interrupted so many times that I was requested to

give oxygen, which checked the vomiting in a very few moments. The operation was then resumed and was very soon terminated, without any more vomiting. An incision about three inches long was made through the abdominal wall and over the right ovary and a careful dissection revealed a cystic ovary, which was removed and ligaments secured with catgut sutures. A further exploration was made and the right kidney was found to be encysted throughout and nothing left of it but a mere shell. This was also removed and the arteries, etc., ligated. The hemorrhage was quite free and continued for some time from some small arteries, requiring a further ligation of some that appeared at first would not require it. The abdomen was then washed out antiseptically, and wound closed with catgut sutures. Iodoform gauze, adhesive plaster and bandages were applied and patient was removed to her room. Oxygen was also used to resuscitate this patient after the operation. She made a good recovery and had no vomiting during her convalescence, nor other unfavorable symptoms.

DISCUSSION.

DR. McHATTON, Macon, Ga.—I think this question of anesthesia is a very important one and there are many different methods of administering them. Anesthesia is always dangerous and I prefer to use either chloroform or ether alone, as when we mix the two, new dangers arise which we can not ascribe to either one. I am rather afraid of the A. C. E. mixture.

DR. HAINES, Cincinnati—I think the point is well taken by the last speaker and I believe it is the general opinion, *i. e.*, that one or the other should be employed by itself. Personally I prefer chloroform. I have seen chloroform administered by midwives, nurses and husbands, and I consider this a practice to be deprecated. When we consider the few deaths as compared with the large number of cases anesthetized daily, I can not but think chloroform is the safest if you can get it pure.

The Secretary, DR. W. L. ESTES—Anything that will add to the safety and to the relief of the burden on the surgeon should be welcomed by the whole profession. The author desires to change the title of his paper, and as he now calls it a safe method it makes it very suggestive. If it is a safe method, it is a great boon. We have often heard of safe methods; for example, anesthesia by direction and the employment of various inhalers. We have begun to question the value of any one appliance or remedy for the administration of the anesthetics. It seems to me that it is the administrator that is the actual actor in the giving which is the safeguard. I think the manner employed in America generally in the giving of anesthetics is to be deprecated, as in most hospitals it is the custom for the general assistant to give it. We all know that if one act in the operation is of importance and requires skill it is the giving of the anesthetic. In England professionals are employed to do this work and nothing else; even there, almost every week we hear of deaths, and if this is true under such circumstances, there must be something in the agent we use which is dangerous. If the reader has introduced something which is absolutely safe, if it be true that oxygen renders it safe, he has, indeed, conferred a boon. One thing that increases this danger is the inhaler, and the one which admits of the greatest quantity of fresh air, I should think, would be the one to use. If the author can prove his theory, it is something which will redound to his credit and others who have suggested it. If he can give us something practicable which can be carried around to every case, it is, indeed, a step in advance. The idiosyncrasies and diseases of the patient should be considered first, and secondly the skill and experience of the operator.

DR. HALL, Milwaukee—There are indications for the use of chloroform and vice versa that are unmistakable and which manifest themselves throughout the time of the action of the anesthetic. I would suggest that a thorough examination before the anesthetic be given would indicate which anesthetic is best and when, if at all, it is advisable to change it. Ether in this country has a reputation for being a very safe anesthetic, and in other places chloroform is so generally used that in the ordinary shop and drug stores ether can not be obtained. This shows narrow-mindedness on the part of the profession. I would say that ether is far more dangerous than chloroform. In the one instance death occurs immediately, while in the other it may take place long after the patient has apparently recovered. The mixture of the natural atmosphere, of course, is a very prominent factor in the safety of the administration. I would like to raise the point that in giving chloroform it is not well to give too much oxygen. The one who has charge of this anesthetic should bring the

patient well under, until a condition between the second and third stage is reached, and hold him there. In that condition it is far less dangerous and there is much less danger of spasmodic contraction of the muscles.

DR. J. McFADDEN GASTON, Atlanta.—I have had a somewhat peculiar experience in connection with anesthesia. Recently in preparing for laparotomy, I observed in my bag a vial, presumably containing 25 per cent. solution of the A.C.E. mixture, which turned out to be carbolic acid and alcohol. The person giving the anesthetic experienced considerable difficulty until it was found where the mistake was. The hands became swollen and the lips were considerably burned. I expected my patient would suffer some inconvenience as the result of this mistake, but she did not. A preparation that I have employed for fifteen years, and which I have found free from danger, is alcohol one part, chloroform two parts, and ether three parts. My anesthetic in former years was chloroform. In speaking of oxygen, if you observe the blood when under the influence of chloroform, the arterial blood will be found of the color of the venous blood. I only know of one instance in which my mixture was fatal and this was in the case of a child who insisted on its being administered every day for a month when changing a dressing. In undertaking to operate in a case of ulceration of the bowel, in which there was marked contraction of the sphincter, I desired to dilate. How far the condition may have been aggravated I do not know, but in the midst of the dilation, there was very difficult breathing and suddenly the patient succumbed. This is the first case of fatal result that I have ever witnessed and I consider it a very serious experience. Some of you may have noticed, the other day, that one of our leading surgeons in Tennessee was arraigned before the court for malpractice for the death of a patient during the administration of an anesthetic, but the court said there was no ground for action. I am not quite sure where we should stand in giving out death certificates in these cases and I should be much puzzled.

DR. J. N. DEHART (closing the discussion).—Many cases of the use of my method have been reported and it is now being employed in over fifty hospitals. It was recently used in a case reported in New York, in which the patient recovered one hour sooner than usual. I have employed chloroform in cases of heart trouble and the patient has been under the influence two and a half hours. The pulse was 114 to 120 for six weeks and at the end of the first hour the pulse had risen to 160. I used oxygen for five minutes and the pulse came down to 145, I gave one-sixtieth of a grain of strychnia and resumed the anesthetic. At the end of one and a half hours the pulse was again 160. I gave oxygen again for ten minutes and it came down to 145. It subsequently rose again to 168. The woman lived for six days and subsequently died of peritonitis, although it was declared at the time of the operation that she could not live through it.

SOME GENERAL CONSIDERATIONS IN RELATION TO THE NATURE AND TREATMENT OF DISEASE.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY LOUIS BALMAT BAKER, M.D.

ERIE, PA.

"Flower in the crannied wall,
I pluck you out of the crannies;
Hold you here, root and all, in my hand,
Little flower—but if I could understand
What you are, root and all, and all in all,
I should know what God and man is."

How profoundly true this is! Given one fact and you have the key to the universe, a formula that can solve all problems, a talisman that will open all the arcana of nature. Be faithful to your one fact and it becomes an unailing test for truth, for nothing that contradicts it, can be true. An isolated fact is an impossibility. Conditions that are unvarying and know no shadow of turning, relate your one fact to all the other facts in nature. And these laws and relations are constant: the same yesterday, to-day and forever. To believe that nature is fickle and capricious, doing a certain thing under definite conditions, one way to-day and another way to-morrow, is to be

left utterly without a guide. There remains nothing on which to depend. It is to be given over to "permanent intellectual confusion." Much of the false reasoning in philosophy and theology, as well as in science, has arisen from infidelity to this great principle, this sure and firm foundation of all correct deduction. The law of gravitation is no more sure and constant, than the laws that rule in the mineral and organic worlds. The crystal forms along definite lines of cleavage, always in the same way under the same conditions; the seed germinates and bursts into bloom and beauty; the bird soars and sings:—all in strict accord with the laws that rule their life and growth. That the gem sparkles, the flower blooms and the bird sings, means simply that they have obeyed the laws of their being.

Let us take the flower, "root and all, and all in all," and see if it will tell its secret. What are the conditions, in obedience to which it has reached its full perfection? First the seed, with its marvelous potentialities, is placed in the soil. It absorbs moisture, swells, bursts its tiny envelope, sends forth its delicate roots in search of food, and presently shoots the green stem above the surface; it unfolds its leaves to the sun, bathes in its warmth, drinks of the rain and the dew, fashions the tender bud and finally shows its full perfection in the beautiful flower.

The conditions that have to do with the proper development of the plant, are mainly six: Light, air, moisture, warmth, suitable soil and protection from parasites.

Light.—Witness the pale and sickly sprout in the dark cellar: the marvelous chemistry of the sunbeam is essential to life.

Air.—Place a plant under a glass receiver, exhaust the air, and it speedily dies. A vacuum would be no less fatal to animal life.

Moisture.—Instance, the Sahara.

Warmth.—The Arctics are as bare of vegetation as the desert.

Suitable Soil.—The food supply; this is of vital importance.

Protection from Parasites.—If a blight attacks the crops or work havoc among the fruit trees, the intelligent farmer no longer attributes it to a mysterious dispensation of Providence. He attacks the invading army of parasites with fire and poison and drives it from the field. Patient investigation, chemic analysis of the plant and of the soil, repeated and faithful observations and experiments, have made agriculture something of a science.

Given a sickly, stunted, imperfect plant, and we know at once that some of the conditions vital to its growth have been violated. The wise gardener seeks to know what condition has been violated; his treatment consists in the correction of the violated condition, and it is simple and rational, the logical sequence of cause and effect. In a word, the scientific method is applied to the study of the nature, structure and conditions of growth of the normal and healthy plant and the treatment of the abnormal bears a strict and definite relation to what has been learned of the normal.

A plea is made for the application of the same method in the domain of medicine. The subject is vastly more complex and difficult, but the principle is the same.

Given a weak, diseased and imperfect man. How is it with us? What is our thought of his condition,

and our idea of treatment? Who of us would be willing to admit how large a part of his treatment is purely traditional, and is based upon the conception that disease is a subtle and mysterious entity or essence, an evil spirit, a foul humor, that exists independent of the body, and is not subject to the ordinary laws of force or matter? A something that exists in such form that on a certain occasion, it was driven out of the body of a man into a drove of swine, causing them to run violently down a hill and drown themselves in the sea.

Is not this still the popular view of the matter? Do not 90 per cent. of the people we meet have some such conception of the nature of disease?

"Doctor, I have this or that disease; what is good for it?" is a daily question. The patent medicine man counts upon this belief with absolute certainty and reaps his harvest of dollars. The Indian medicine man, practicing his fearful incantations, is in accord with this theory; and as a piece of the same philosophy applied to astronomy, we have the tales of how eclipses and comets are made to flee before the dreadful din of the Chinese tom-tom.

But we no longer consult the astrologer in regard to the stars. Copernicus made his occupation an absurdity. The telescope has replaced the horoscope. The weird alchemist bending over the alembic, seeking and ever seeking to transmute the baser metals into gold, and to fabricate the mysterious elixir of life, stands in sharp contrast with a master of modern chemistry. Lavoisier placed alchemy among the mythologies. Copernicus, in establishing the heliocentric theory in the place of the geocentric, readjusted the intellectual outlook of all the philosophers. Lavoisier, in the discovery of oxygen, laid the foundation of the most exact of all the sciences, and the immortal Harvey in 1628, when he discovered the circulation of the blood, gave to our profession a like master thought.

That view of disease which regards it as something extraneous and unrelated, is the historic and philosophic equivalent of astrology and alchemy. It represents the medical aspect of the tendency, universal among all primitive peoples, to personify all the powers of the earth, sky and sea.

It is not contended that modern intelligent medical men base their conception of disease on this theory; and for that very reason a protest is entered against a therapeutics that is based upon it, and that has no possible explanation aside from such a conception. The protest is directed against that form of therapeutics which consists in the indefinite, promiscuous, internal, external and eternal administration of drugs, to the almost total neglect of sanitation and hygiene.

Drugs have their proper use and there is no disposition to underrate the benefit derived from them, but most assuredly they have their abuse. Four or five thousand remedies! What an appalling and ever increasing list! Reserve twenty-five or thirty of them and the remark of Dr. Holmes will truthfully apply to the remainder, "that if medicines were cast into the sea, it would be better for mankind and worse for the fishes."

Health means sound structure and normal function. As with the plant so with the man, the law of life is the same. Health, mental, physical and moral, depends upon obedience to law. Disease means transgression. Nature's laws operate along straight lines. The life that is ordered parallel to these lines is safe. He who

crosses them is pierced. Nature is impartial and merciless. She does not contemplate the individual, but the race, hence the awful fact of heredity, so splendid in the right direction, so terrible in the wrong.

The best physicians are those who have the keenest eye for bad surroundings and hurtful habits, and they use the fewest medicines. Doctor and doper are not necessarily synonymous terms.

Is it not true of us as a profession, that we have depended too much upon drugs? Are we not quite easily convinced that we have done our entire duty to our patient, when we have prescribed the medicine best calculated to relieve the diseased condition?

To illustrate: Miss C., student at a fashionable boarding school, a young lady broken in health by an artificial life and wrong methods of education, comes to us. We know the whole story before she has said a word. Anemia, dyspepsia, neuralgia, palpitation, dysmenorrhea, constipation, insomnia and headache are the prominent factors in the case. Shall we rely upon iron, arsenic, strychnia, cod-liver oil, pepsin, hydrochloric acid, strophanthus, nitro-glycerin, digitalis, aloes, jalap, cascara, bromid of potassium, chloral, belladonna and opium, and so on ad infinitum? And that headache!

Drugs galore, some fifty or more,
And still the head aches to distraction,
The eyes! did you say? I'll try anyway,
It yields to a proper refraction.

To dismiss such a patient with a fine Latin prescription calling for some of these drugs or a combination of them, is not to meet the indications. Is it not vastly more important than any or all medicines you may use, to insist upon it that your patient obeys the following rules, briefly:

Proper food, with all that is implied as to quality, quantity and regularity of meals.

Exercise, systematic, in the open air, plenty of it; walking, riding, rowing, the wheel, anything and everything so that the patient is kept out of doors.

Proper clothing, and so adjusted as not to obstruct the circulation, or hinder the free use of all the muscles.

Bathing; there is no tonic in the pharmacopeia equal to a cold dash and a vigorous rub.

Healthful occupation; at 87 Gladstone says: "Work, work, if you want to keep young."

These are the important and essential things, both in restoring and maintaining health.

Drugs have constituted too large a part of our equipment, and the tendency has been to rely upon them to the exclusion, or at least the neglect, of the more important measures that are included in the one word, hygiene. The effort should be continually toward the establishment of a more logical relation between our therapeutics and the morbid conditions under treatment.

The thesis then is, that disease is not to be considered as something unrelated to the orderly sequence of events, but as something related by definite and distinct conditions to the natural order of things; and it is to be investigated and explained as is any other fact in natural history.

Anatomy, physiology, chemistry, physics, biology and bacteriology; proficiency in these things gives an understanding of the normal, and it is only thus that the abnormal can be recognized and combatted.

The study of medicine is becoming intensely interesting. The voice of the bacteriologist is being heard

in the land. The chapters in etiology are being rapidly rewritten. Theories and "opathies" are being replaced by demonstrations. Splendid are the results already attained! Much remains to be done, but the time is not far distant when the expression "The Science of Medicine" can be used without a mental reservation.

NERVOUS SHOCK AND DISEASE OF THE NERVOUS SYSTEM AS A CAUSE OF PERNICIOUS ANEMIA.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY JAMES B. HERRICK, M.D.

CHICAGO, ILL.

It is the object of this paper to direct attention to nervous shock or disease of the nervous system as a possible, or probable, exciting cause of grave or pernicious anemia. My attention was called to the relations between these conditions by the following case:

The patient, Mrs. M., white, 63 years of age, claimed to have been in good health up to November, 1893. She had rosy cheeks, was plump, weighed 137 pounds, led an active, busy life as a quasi-practitioner of medicine. She scarcely knew what it was to be confined to bed save when her children were born, five of whom she had brought into the world alive and healthy. She had never miscarried and there was no other evidence leading to the suspicion of syphilis. Her father had lived to the age of 87, to die an accidental death. Her mother succumbed to pleurisy at 63. One brother had died from some cardiac trouble and one sister from asthma. Two brothers and one sister were living.

In November, 1893, she fell on the sidewalk, hurting her back and left side. To use her own words: "The hurt extended from the back of the neck down the left side and left leg." She walked home, but from the time of this injury she found herself weaker, both physically and mentally. She was obliged to lie down the greater part of the day, and thought she was becoming paralyzed. Soon the legs began to bloat; and she would, upon sitting up for a short time, feel dizzy and perhaps faint. The patient became unable to walk for any great distance; had difficulty in picking up small objects such as a pin. The skin became paler; the appetite, notwithstanding, remained good; the bowels were constipated. She was often quite thirsty.

On admission to the Presbyterian Hospital June 30, 1894, her complaint of somewhat vague pain, of weakness of the arms and legs, and mental deterioration, for all which she assigned the injury as the efficient cause, coupled with the fact that there could be discovered no evidence of organic lesion to account for such phenomena, and also that she referred often to a \$2,000 accident insurance claim that she had placed in the hands of a lawyer for collection, all this aroused a suspicion of exaggeration of symptoms as in railway spine, if not of malingering.

The increasing pallor of the skin led later to an investigation of the blood and a more thorough examination of the patient. I condense the results of several examinations.

Physical Examination Nov. 8, 1894.—Skin and mucous membranes of a lemon-yellowish white. Conjunctivæ show light yellowish tinge. Skin is dry,

wrinkled, panniculus adiposus scanty. Patient talks rather slowly, as if taking a long time for framing answer and separate words. Speech reminds one of scanning speech of insular sclerosis. She moves hands and legs slowly and somewhat uncertainly; appears weak and unable to walk or stand unsupported; complains of great dizziness on being put in erect posture. Hair is gray, thin and falling out fast; ears and nose negative; tongue pale, flabby, not tremulous, protruded in median line; fetor *ex ore*; frequent spasmodic contraction of lower portion of orbicularis palpebrarum. Right eye beginning cataract; numerous retinal hemorrhages; left eye, retinal field practically the same; in right eye six hemorrhagic areas counted, in left twelve. The existence of retinal hemorrhages was confirmed by Dr. Alfred Hinde, who kindly examined the eyes for me. External jugular pulsates synchronously with apex-beat as does a vein (probably a perforating branch of the internal mammary) running just to the right of the sternum and parallel with it for its upper one-quarter. The chest is slightly flattened, of moderate length, intercostal spaces rather wide; respiratory movements regular, fairly deep, eighteen to the minute. Apex-beat faintly seen and felt in the fifth interspace just inside the left mamillary line; palpation otherwise negative. Percussion reveals no increased area of cardiac dullness. Pulmonary resonance on the right side in the mamillary line on expiration as low as to the sixth rib, on inspiration over seventh rib. Respiratory sounds are normal save an occasional moist râle; (in the last two days has "taken cold"). Systolic blowing is heard over entire precordia, best at apex; systolic hum also over vessels of neck. Abdomen is flabby, marked with lineæ albicantes; occasional peristaltic movements in region of umbilicus and to right of same. Edge of liver is felt very indistinctly about one inch below costal arch; inguinal glands are palpable but not perceptibly enlarged. No tumor mass or point of tenderness is found on palpation. Liver dullness is heard in median line, one-half way between ensiform cartilage and umbilicus; area of splenic dullness increased in posterior axillary line reaching as high as to the eighth rib; Stomach resonance apparently increased in area. Stomach reaches below umbilicus (gastroptosis); it appears moderately enlarged. Lesser curvature apparently made out between ensiform and umbilicus. After test breakfast (Ewald) no free HCl, no mucus, no remains of previous meal are present; pepsin uncertain; no lactic acid by Uffelmann's test. Lower extremities are moderately edematous; rectum negative, no parasites in stools; pelvic organs negative; bones negative, no tenderness. No evidence of organic or local nervous lesions can be made out. Sensation seems to be perfect, the reflexes normal. There is no paralysis. The bowels are inclined to constipation. There is no great frequency of urination, no difficulty in urinating, or irritation from urine. Movements of muscles are slow and feeble, not coördinated with certainty. Raises dynamometer to 10 with either hand. Urine is 1012, 30 to 50 ounces; no albumin, no sugar; solids, 660 grains; no formed elements. Blood is pale; marked poikilocytosis, microcytes and macrocytes; few nucleated red; megaloblasts, *i.e.*, the large nucleated reds, few; leucocytes increased relatively; many lymphocytes; number of red globules to cubic millimeter 666,666; hemoglobin (Fleischl) 25 per cent.; no parasites. I desire to acknowledge the kindly aid of the

late Dr. D. D. Bishop. Several of the numerous blood examinations were made by him.

I present temperature chart showing continuous irregular fever.

The patient remained in the hospital, though not under my immediate observation, until the middle of the summer of 1895. On increasing doses of arsenic there was a perceptible improvement, both as regards the subjective and objective symptoms. There was less dizziness, more certain movements of the hands and legs, clearer mind, greater strength. The blood count gradually changed so that on March 22, 1895, the hemoglobin was 80 per cent. and the red corpuscles 2,575,000, with no increase in the white. A severe attack of bronchitis or influenza seemed about to carry off the patient, but she rallied from this and finally left the hospital at her own request. I am unable to state facts concerning her subsequent history.

The case was seen by several physicians and all failed to locate any organic cord or brain lesion or any malignant growth.

The intense pallor of the skin, the subjective sensations of dizziness and palpitation, the great mental and bodily weakness, the retinal hemorrhages, the anemic murmurs, the enormous reduction in the number of red corpuscles with such marked varia-

regarded as progressive pernicious anemia where there is a great disproportion between cause and effect. (Bd. iv. S. 22.) A case, therefore, of atrophy of the stomach or of anchylostomum disease where the symptoms of the anemia completely overshadowed those of the primary trouble he might class as progressive pernicious anemia. It seems better, however, with most writers to regard only the cases as progressive pernicious anemia in which the affection is a primary blood disease, in which so far as our present knowledge of the etiology and pathology goes, no change is found during life or after death save in the blood or the hematopoietic organs. That this is usually fatal is well known. Recoveries, however, are occasionally recorded. The term progressive pernicious had better be discarded, and the term employed first by Addison, primary essential anemia, substituted.

Looking upon this case as one of primary essential anemia, there remains to be noted the interesting connection between the injury with its nervous shock and the anemia. The patient and her friends assert that from a condition of apparent health, she almost immediately following the injury became an invalid, weak, dizzy, easily fainting, with swollen limbs, pale skin, in a word, anemic. Just how nervous shock produces anemia I will not attempt to say. Yet, if through a shock to the nervous system the secretion

tions in their form and size, the presence, though in small numbers, of nucleated corpuscles, the increased globular richness in hemoglobin, the corpuscles being reduced to 13 per cent., while the hemoglobin was reduced to but 25 per cent., the continued irregular fever, the temperature ranging from 97 to 102 F., gave an almost typical symptom-complex of the so-called progressive pernicious anemia of Biermer, or the primary essential anemia of Addison. Enlargement of spleen and liver have been often noted in these cases as well as venous pulsation.

But many cases clinically perfect as progressive and pernicious in character and apparently due to some primary disease of the blood or of the blood-making organs, have been found postmortem to have some organic lesion overlooked during life that should be regarded as primary. Thus a hidden carcinoma, an intestinal blood-consuming or toxin-producing parasite, as the anchylostomum duodenale or the bothriocephalus latus, an atrophy of the gastric and intestinal glandular structure may explain an apparently primary anemia. Some authors incline to put these cases in the category of the essential anemias because of the predominance of blood changes and blood symptoms. Thus Eichhorst says that only those deuteropathic or secondary anemiae are to be

of the sweat glands, of the gastric glands, or of the kidneys can be checked or increased, if the heart's action can become rapid and irregular, or perhaps cease altogether, if a chorea or an exophthalmic goitre can be roused to activity, it can be assumed that the function of the blood-producing organs may become perverted, and this suddenly, through the influence of a deranged nervous system. I recall a case of cerebral hemorrhage with aphasia and hemiplegia in which there was fatal anemia; also a fatal case of anemia following upon a sunstroke.

I am inclined to rule out atrophy of the glandular tissue of the stomach, largely from the absence of any symptom indicating a previous catarrhal inflammation, though the emaciation different from the well-preserved condition of pernicious anemia, the absence of mucus and of free hydrochloric acid and the enlargement of the stomach might seem to point in that direction.¹ There was certainly not present the small contracted stomach with exuberant development of connective tissue—cirrhosis ventriculi. The dilatation, more apparent than real, because of dislocation of the organ, was probably, as not infrequently occurs, due to

¹ Some, for example Strümpell, regard the changes in the glands of the stomach as secondary to the condition of anemia. Likewise the changes in the cord and other nervous structures.

relaxation of the atonic stomach walls. I believe there was no hidden carcinoma as the cause of the anemia because of the comparatively sudden onset; the absence of subjective or objective local symptoms; the unusually severe oligocythemia, reduction of erythrocytes to 1,000,000 per cubic millimeter being unusual in the terminal anemia of carcinoma; the marked improvement under arsenic, the improvement lasting for at least six months, and being scarcely reconcilable with a carcinomatous anemia after it had reached a stage indicated by a blood count of only 666,666; the retinal hemorrhage and the absence of cachexia.

Whether or not an organic disease of the brain or cord or of the sympathetic or peripheral nerves was present no one who saw the case would say. The interesting researches of Minnich in this connection are recalled by some of the symptoms.

While nervous shock or disease of the nervous system is not recognized in many of our text-books as an important etiologic factor in pernicious anemia, a number of cases are reported in which this is the assigned cause.

Under this head are not included those cases of nervous diseases as complications or sequelæ of pernicious anemia, such as degenerations of the posterior columns or the other parts of the cord, etc., and which Minnich has recently gone into so fully. (Cf. also Lichtheim, Trechsel, Burr, etc.)

Eichhorst quotes the case of an author who, after a most severe mental strain, succumbed to a fatal anemia.

Curtin, in 1885, under the title "Nervous Shock as a Cause of Pernicious Anemia," reports the case of a woman, 38 years of age, who was unexpectedly brought face to face with the body of her suicided brother with his throat cut. From that time health began to fail, and in four years and two months she was dead of a grave anemia. No blood examination; no autopsy.

2. A young lady was suddenly and brutally informed of her brother's death. Nervous prostration followed for many months, then pernicious anemia and death.

3. Practice of Dr. Musser: A woman, aged 42, after an attempt at her own murder by her husband, became nervous, excitable, almost insane; gradual failure of health, pronounced anemia; death in three years.

Curtin quotes also the case of a woman becoming profoundly anemic following fright at the house catching on fire. He also quotes from Mackenzie, who cites the case of Sir H. Marsh, where the young lady, who accidentally poisoned her father, was overwhelmed by grief, took to bed and died of anemia. Also the case of a young man who saw a child run over in the street, was greatly shocked, began to grow anemic; no organic lesion postmortem.

Under Sir William Gull, a young man died in Guy's Hospital of extreme anemia that had developed after he had been attacked by a sheep in a field.

Musser in 1885 gave a résumé of thirty-nine cases of pernicious anemia up to that time reported in America, and quotes cases of Curtin, Osler, Pepper and himself, where anemia seemed to be due to nervous shock.

Hutchinson cites cases in which nervous influence seemed to him to be the exciting cause. 1. A case of his own where mental worry over the death of a wife was the cause. 2. Case in consultation where a man-

ufacturer who had worried about business had become anemic, apparently from no other cause than business worry. 3. Four daughters died in one week of smallpox. The father, apparently from the shock and the excessive grief, developed pernicious anemia.

Dr. Brower cites a case of pernicious anemia developing in a previously healthy young woman following a railway accident. Death in six months. He also calls attention to mental worry as an exciting cause of the milder grades of anemia and of chlorosis, and is authority for the statement that in a student worrying and apprehensive about the approaching final examination, the hemoglobin became reduced to twenty per cent.

Schüle, in three cases of pernicious anemia in the insane, seemed to see some genetic relation between the incurable cerebro-spinal lesions and the progressive anemia. He quotes the experiments of Goltz, Heubel and Von Tarchanoff as tending to prove the influence of the nervous system on blood formation, apart from the trophic influence of the spinal cord.

Macphail also describes pernicious anemia as it developed in two insane patients.

Holst believes that through neurasthenia the secretory nerves and the trophic nerves are influenced in such a way that blood deterioration results. He regards the anemia therefore, in many cases, as a result and not the cause of the neurasthenia.

Hale White refers to a patient who fell on the ice. For fourteen days no symptoms, then weakness, numbness in legs and progressive severe anemia; apparent recovery.

Among those who assign to the nervous system, chiefly through what we must, for want of a more accurate term, call nervous shock, a certain rôle in the production of anemia may be mentioned Heiberg, Fabre, Germain Sée, Trouseau.

A number of observers believe there is some causal connection between lesions of the nervous system and pernicious anemia. Thus Saaski believes the gastrointestinal form depends on nerve atrophy in Meissner's and Auerbach's plexuses. These changes he is inclined to look upon as primary and not as secondary to the anemia, though others reverse the order of pathologic change. He examined two cases and forty-eight control cases.

Brigidi examined the body of a woman, aged 53, dead after two years of anemia. The only weighty postmortem finding was an inflammatory and fatty degenerative change in the celiac ganglia. He thinks the influence on the circulation of the digestive tract might explain the poor digestion and consequent anemia.

Pokrowski, autopsy on a case of pernicious anemia, found changes in cerebellum, fourth ventricle and medulla, and was led to conclude that the finding in the central nervous system must have had an influence, if not the sole influence, in producing the anemia.

Banti refers to a group of anemias—anemia ganglionare—in which he believes the primary change is in the sympathetic nervous system.

Little also regards many cases as due to an irritation of the vaso-motor system.

I feel warranted from my study of this case and a perusal of the literature bearing upon this subject, in drawing the conclusion that in some cases of pernicious anemia there is a causal connection between shock or injury to the nervous system and the result-

ing anemia. Whether such shock acts by interference with the nervous mechanism of the digestive organs, the stomach, intestines, liver, pancreas, the ultimate result being a severe anemia, or whether through altered nervous influence, there is abnormal performance of function on the part of the hematopoietic organs, it is impossible to say. In assigning to nervous shock an influence in the production of anemia it is not necessary to regard it as the sole cause or even the prime cause. Just as in the case of pneumonia we look upon the pneumococcus as the main cause of the disease, but yet regard exposure to cold as an exciting cause that favors the localization or pathogenic action of the specific organism, so in the case of pernicious anemia, the nervous shock may in some way merely favor the action of some otherwise inert microorganism or toxin, that under these altered circumstances produces a profound or even fatal anemia.

DISCUSSION.

DR. H. A. WEST, of Galveston, Texas—One fact in explanation of the influence of nervous shock in producing anemia perhaps was not fully brought out. I refer to the influence of nervous and mental shock upon the digestive organs; upon the appetite, causing anorexia, and such disturbances of the digestive processes as would account to a considerable extent for these anemic conditions. One can readily understand the philosophy of such a *modus operandi*. That the appetite is interfered with, assimilation and metabolism are disturbed, and anemia follows.

DR. J. H. MUSSER, of Philadelphia—Recently two cases of pernicious anemia have come under my care which were secondary to, if not due to, nervous influence, anxiety and grief followed by digestive disturbances. They would seem to indicate nervous shock bringing on gastro-intestinal disorders, with malnutrition and anemia. This view is also in accord with the studies of the pathology of pernicious anemia by Hunter and others, tending to show that it is related to, and is largely secondary to, conditions of the gastro-intestinal tract. The poisonous agent probably escapes the liver, is not destroyed as it should be, but enters and acts directly upon the blood, producing anemia. It seems to me that this is the train of processes going on, and with such a view it is proper to say that shock and other nervous influences of a functional character rather than those of organic change act in producing the anemia. I have never seen pernicious anemia occur in organic disease of the nervous system, but shock and other nervous influences said to be of functional character may be promotive of that condition.

DR. J. WELLINGTON BYERS, of North Carolina—It seems to me that a number of conditions may bring about that vicious circle, if we may so call it, of malnutrition which results in pernicious anemia. Nervous shock may be one of these.

DR. LOUIS FAUGERES BISHOP, of New York—I think this paper is very interesting as illustrating in another direction the fact that the nervous system presides over the chemistry of the body in whatever part of the body the chemistry takes place. We see that not only in anemia but also in gout. Gout is a disease which is very closely connected with a depressed condition of the nervous system, and the chemistry of the body seems to go wrong because the nervous system is not in condition to exert proper control. There is one interesting fact in connection with this control of the chemistry of the body by

the nervous system, and that is the value of strychnin in a great many varied conditions. I think this value, not only in the treatment of anemia, but in the treatment of a great many diseases is due to its power of stimulating the nervous system to perform better its work of controlling the chemistry of the body.

A NOTE ON THE ACTION OF APOLYSIN.

Read by Title before the Texas State Medical Association at Fort Worth, April, 1896.

BY DAVID CERNA, M.D., Ph.D.

Demonstrator of Physiology and Lecturer on the History of Medicine in the Medical Department of the University of Texas.

Recent literature concerning antipyretics and analgesics has brought to the notice of the profession several new drugs, among which *apolsin* seems to occupy a prominent place. Through the courtesy of a new York drug firm that kindly furnished me with a considerable amount of the new medicament, I have been enabled to conduct a series of experiments in the physiologic laboratory of the University of Texas, at Galveston, the results of which I shall endeavor to embody in this brief report.

Apolsin is a substance closely related to phenacetin. Like the latter drug apolsin contains parphenetidin. In phenacetin, however, the parphenetidin of the amide group (NH_2) one atom of hydrogen is replaced by an acetic acid radical; while in apolsin the atom of hydrogen of the parphenetidin of the amide group is substituted by a citric acid radical. It may be said in this connection, that a combination of phenetidin and citric acid under the name citrophen, or citrate of phenetidin, has been referred to by Benario as possessing medicinal virtues.¹ But according to Seifert² although one molecule of citric acid can be combined with phenetidin to form the so-called citrophen, it can also be combined with two molecules and with one molecule of phenetidin, respectively, to form different substances. Treupel³ has experimented with citrophen, and found it to be poisonous like all the salts of phenetidin. On the other hand, it is claimed that apolsin is not related to the citrate of phenetidin, or citrophen, but that it contains two complete citric acid groups, and is practically non-poisonous, being not a simple salt of phenetidin, but a phenetidin permanently combined in an anilid-like form. The innocuousness of apolsin has apparently been demonstrated by the investigations of Nencki and Jaworski.⁴ Further, it is asserted by Seifert that carbonate of sodium causes no changes in apolsin, while the addition of that same sodium carbonate to citrophen produces an immediate separation of phenetidin as a free poisonous base. Hildebrandt,⁵ who has also studied the chemical relations of both citrophen and apolsin, affirms that these two substances differ chemically from one another in this, that in the latter, apolsin, one molecule of phenetidin is associated with one molecule of citric acid with the production of water; while in the former, citrophen, three molecules of phenetidin are combined with one of citric acid but without the production of water; that the relation of citrophen to apolsin is like that of the lactate of parphenetidin to lactophenin.

Apolsin appears in the form of a white or yellowish-white crystalline powder having a faint smell and

⁵ Centralbl. für inn. Medizin, Nov. 9, 1895.

an acid taste; is readily soluble in warm water, and in cold water in the proportion of one part to fifty-one, or at most fifty-five. This new drug is also freely soluble in alcohol and cold glycerin. Apolysin melts at 72 C. (161.6 F.) Placed upon platinum shell and heated, apolysin burns up completely without leaving any residue, and further experimentation regarding its chemic behavior, with nitrate of silver, sulphuretted hydrogen, and sulphid of ammonium, shows that it contains no metallic substance. Treated with concentrated hydrochloric acid and chromic acid, it gives a ruby red color. But apolysin combines with metals to form salts; it also forms combinations with caffein, quinin, sodium, magnesium, lithium and other substances. The formula of apolysin is given as follows:

In an experimental study, previously referred to, Nencki and Jaworski⁶ found that apolysin even in considerably large doses was non-poisonous to frogs and rabbits. In the former class of animals apolysin injected hypodermatically in the proportion of from 0.0005 to 0.004 gram to 1 gram of the body-weight, produced absolutely no toxic effects. The same results were obtained in the case of rabbits. To one of these rodents, weighing 1345 grams (47 ounces), was administered 3.5 grams (54 grains) of a 10 per cent. watery solution of apolysin, that is, in the proportion of a little over 2½ grams per kilogram of the body-weight, but no bad effects were observed. Hildebrandt,⁷ like Treupel, says that citrophen, identical, as has been stated, with the ordinary citrate of phenetidin, is poisonous to rabbits; while the toxic properties of apolysin are practically *nil*, and certainly much less than those of phenacetin. He affirms, indeed, that 8 centigrams (1¼ grains) of apolysin, injected subcutaneously, caused no ill effects on white mice, while 3 centigrams (2-5 of a grain) of phenacetin, administered to the same class of animals, produced the characteristic toxic effects of phenetidin.

I have been able to corroborate some of these statements in regard to the general action of apolysin on dogs, and as illustrations I append the following experiment:

Experiment 1.—Dog weighing about eight pounds. Exposed external jugular vein and injected into it 5 grains (3 decigrams) of apolysin dissolved in water at 10 A.M., 10:15 A.M. no effect, and gave another dose of 10 grains (6 decigrams). This injection was followed a few moments later by a slight increase in the number of respiratory movements, but this effect soon disappeared and the animal continued well. At 10:45 A.M. a third dose of 15 grains (1 gram) was administered. A short time afterward the canine began to breathe a little faster than usual, and then sought a corner of the room where he remained for about an hour, very quiet; in half an hour later the dog was as lively as ever. At 3 P.M. injected 15 grains (1 gram) more, and with the exception of the respiratory disturbance alluded to, and a tendency of the animal to remain quiet, no other marked effects were noticed in the course of three hours, by which time the dog seemed as well as ever.

In the experiments that follow the animals were first anesthetized, and then, after the external jugular vein was exposed and prepared for the injections, the carotid artery was connected with the kymograph in order to better observe the effects on the circulation and the respiration. Observations were made at the same time regarding the bodily temperature, this being

taken at the rectum by a thermometer with centigrade scale. In all these experiments a five per cent. watery solution of the drug was used.

Experiment 2.—Dog, weight twenty pounds. An injection of 5 c.c. caused no alteration in pulse, blood-pressure or respiration in the course of fifteen minutes. A second injection of 10 c.c. of apolysin solution was followed by a scarcely perceptible fall of the arterial pressure accompanied with a slight increase in both the rate of the pulse and the number of respirations, these effects soon passing off, however. Three more doses of 5 c.c. each were given at about twenty minutes intervals, but with the exception of the same slight disturbances like those noticed after the second injection, no marked permanent changes were observed either in the circulation or the respiration. The blood appeared to retain its normal character. During the experiment the animal seemed quiet as if under the influence of some nerve-depressing agent. The temperature was slightly reduced. The dog was finally killed with chloroform.

Experiment 3.—Dog weighing about twenty-eight pounds was used. The first intravenous injection of 10 c.c. caused an immediate fall of the arterial pressure, a temporarily increased but soon followed by a diminished beat of the heart, and an acceleration of the respiratory movements. The blood pressure and the heart's action shortly returned to the normal condition and remained so for fully an hour. A second injection of 5 c.c. produced no circulatory changes, but the same disturbances in the respiratory function previously observed were again produced. An injection of 10 c.c. given a few moments later was followed by a rapid fall of the blood pressure and reduction of the pulse-rate, which changes, however, soon disappeared. The respiration was markedly affected, the rate of movement becoming almost twice as high as in normal circumstances. The thermometer at the rectum showed, about twenty minutes after the last injection, a fall of the bodily temperature amounting to a little over half a degree. No changes observed in the blood itself.

Experiment 4.—A small dog, weight about ten pounds. Gave repeated intravenous injections, at short intervals, up to about 3 grams (45 grains). This finally caused death by a simultaneous arrest of the respiration and the heart, the symptoms of asphyxia being particularly marked. Death was preceded by considerable hematuria and cyanosis, with a distinct discoloration of the blood.

A better idea can be obtained, perhaps, of the actions exercised by apolysin on the circulation and the respiration, from a description of some of these experiments in tabulated form, as follows:

Experiment No. 5. Dog; weight, 15 pounds.

Time. m. s.	Dose. Grams.	Pressure. mm.	Pulse. per min.	Resp. per min.	Remarks.

A close examination of the preceding experiments

⁶ Loc. citat.

⁷ Loc. citat.

shows that small or even medium-sized doses of apolysin cause no marked effects on the circulation. Large quantities, however, reduce both the pulse and the arterial pressure. The same phenomena are still produced after previous section of the pneumo-gastrics, as well as after peripheral paralysis of the vagi by atropin, as shown in the following experiment:

Experiment No. 7. Dog; weight, 22 pounds.					
Time. m. s.	Dose. Grams.	Pressure. mm.	Pulse. per min.	Resp. per min.	Remarks.

28:00		98			Involuntary discharge of bloody urine; respiration labored; pulse very irregular; cyanosis.
35:00					Animal dies from a simultaneous arrest of its heart and respiration.

From the foregoing evidence it can be said that the reduction of the pulse rate is independent of any excitation of the cardio-inhibitory nerve centers, and is chiefly due to a cardiac influence. The changes observed on the pulse and the arterial pressure appear also to show that the latter falls owing mainly to an action on the heart directly. I do not believe the vaso-motor system is affected by apolysin, and if there be any influence exercised even in massive doses, it must be slight and subservient to that produced upon the heart itself. I could not, however, determine this point positively, since my experiments by severing the spinal cord were unsuccessful.

Respiration: As seen in the course of the above experiments, the increase in the number of respiratory movements produced by apolysin in both normal animals as well as those in which both vagi had been previously paralyzed by atropin and by section, was an usual occurrence. The action is, therefore, central.

Temperature: Apolysin appears to exercise a slight influence on the bodily temperature of normal animals, except, perhaps, in very large doses. The accompanying experiments are self-explanatory.

Febrile temperatures, on the other hand, are easily reduced by apolysin even in comparatively small doses. For these experiments I first produced artificial fever in dogs, by intravenous injection of putrid blood; and in a second series of experiments the blood and the drug were administered together and

the effects observed. For purposes of illustration I detail only one experiment, as follows:

Experiment 11.—Dog weighed thirty-two pounds. First day: In the normal state; at ten A.M. the rectal temperature was 39.1 C.; 11 A.M., 39.1; 12 A.M., 39.2. In the fever state, 1 P.M., 39.2. Injected into the jugular vein three drops of putrid blood: 1.30 P.M., 39.3; 2 P.M., 39.8; 2.30 P.M., 40.3; 3 P.M., 41.3; 4 P.M., 41.8.

Second day: 9.30 A.M., 39.4. Injected five drops of putrid blood; 10.30 A.M., 41.3. Injected three drops of putrid blood and 10 c.c. of apolysin solution; 10.45 A.M., 40.8; 11 A.M., 39.6. Injected three drops of blood and 10 c.c. of apolysin solution; 12 M., 39.3; 1 P.M., 39.2; 2 P.M., 39. Animal sacrificed with chloroform.

The same results were obtained in other similar experiments. But whether this reduction of febrile temperature by apolysin be the outcome of any direct or indirect action on the heat centers I am not prepared to state. In order to determine this point calorimetric studies are necessary. It is probable, however, that the influence of apolysin in reducing febrile temperatures is similar to that of phenacetin, with which the drug under consideration is identical, the antithermic effects depending on the separated paramidophenol.

Clinical Uses of Apolysin.—Apolysin has been employed in practical medicine not only as an antipyretic but as an analgesic as well. In both instances the drug is alleged to have given satisfactory results.

I have had no opportunity to try the drug in febrile patients, but in two cases, one of lumbago and the other of muscular rheumatism, in which pain was a prominent symptom, apolysin produced a prompt and quite effective relief.

Nencki and Jaworski have used the drug somewhat extensively, it seems, in disease to test both its antipyretic and analgesic properties. Observations were made in the treatment of croupous pneumonia, scarlet fever, typhoid fever, puerperal fever, influenza, pyemia, follicular tonsillitis, erysipelas, sciatica, head-

ache and various kinds of neuralgia. The authors affirm that in the febrile affections mentioned, apolysin exercised a powerful antithermic action; that in neuralgic troubles it diminished the hyperesthesia, shortening the individual attacks, and at the same time alleviating the symptoms almost entirely. It is also stated by the same clinicians that owing to the fact that apolysin is easily decomposed by the gastric juice, the drug is contraindicated in hyperacidity of the stomach, and that it ought not to be given if the latter organ be empty. Under these circumstances, however, according to Hildebrandt, apolysin may be administered in combination with bicarbonate of sodium, in the form of tablets, which effervesce on being dissolved in water, owing to the liberation of carbon dioxide.

All the authors here quoted seem to regard apolysin as superior to phenacetin, owing to its solubility and to its non-poisonousness even when ingested in comparatively large quantities: that the depressing effects upon the heart, which are distinctly seen in phenacetin due probably to the phenetidin which the latter remedy contains, are not observed under the action of apolysin.⁸ Again, it is held that the innocuousness of apolysin is probably due to its similarity to citric acid, obeying the law expounded by M. von Nencki. According to this law the entrance of an acid group in a poisonous substance diminishes or entirely destroys its lethal properties. It is further asserted by these authors, especially by Seifert, as will be remembered, that apolysin is practically non-poisonous because it is not a simple salt of phenetidin, but a phenetidin permanently combined in an anilid-like form, and yet Nencki and Jaworski say that apolysin is easily decomposed by the gastric juice. The drug appears to be decomposed in the organism, since these latter authors, as the result of experimentation, affirm that apolysin taken in daily doses of 45 grains (3 grams) is, in part at least, eliminated in two forms, that is, as paraamidophenol and paraphenetidin.

It has been shown by Treupel⁹ that paraamidophenol, like paraacetamidophenol, when injected intravenously into dogs in the proportion of from 15 to 30 grains (1 to 2 grams) for every 2.2 pounds (1 kilo) of the body-weight, produces toxic effects, these being manifested by clonic and tonic spasms of the extremities, a rapid respiration, and paralysis of voluntary motion. In the same class of animals, these substances in the proportion of 7.5 grains (0.5 grams) per 2.2 pounds (1 kilo) of the body-weight, caused somnolence, weakness in the hind extremities, cyanosis, vomiting accompanied with an increased secretion of tears and saliva, and the production of methemoglobin in the blood. It is said, moreover, that the reduction of fever in the human subject by both paraamidophenol and paraacetamidophenol is accompanied with chilliness, vomiting and tinnitus aurium.

But be all this as it may, and although fully agreeing with the statements of the authors referred to, as to the innocuousness of apolysin even when ingested in large amounts, and notwithstanding the assertion that the drug is usually reluctant to part with the phenetidin which it contains, care, I believe, should be exercised in the administration of apolysin. It is true, no case of poisoning by this agent in man, has been reported as yet, and although Nencki and

Jaworski, Seifert and Hildebrandt have observed no lethal effects, I, myself, have seen not only bad results but death also in the lower animals following the ingestion of apolysin. The results of Experiment 4 are here recalled. In this experiment intravenous injections of the new medicament finally caused death by a simultaneous cardiac and respiratory paralysis, the fatal issue being preceded by considerable hematuria, cyanosis and marked symptoms of asphyxia, changes, be it remembered, similar to those produced by paraamidophenol and those caused by paraphenetidin. Therefore, while I do not consider apolysin a toxic agent in ordinary therapeutic and even larger doses, I must certainly caution against its injudicious administration as a routine practice in all those cases calling for antipyretic and analgesic remedies. Apolysin may be given to adults in single doses varying from 15 to 30 grains (1 to 2 grams) by the mouth; to children in proportionate amounts according to age.

SOCIETY PROCEEDINGS

Medical Society of the State of Pennsylvania.

Forty-sixth annual Session of the Medical Society of the State of Pennsylvania, held at Harrisburg, May 19 to 21, 1896.

DR. R. W. STEWART, of Pittsburg, read a paper on
THE TECHNIQUE OF SUPRAPUBIC CYSTOTOMY.

This is indicated in vesical calculus where the stone is too large or hard to crush and remove by litholapaxy or in the modified operation of crushing by means of median perineal incision. Its general adoption has been deterred by its supposed dangers, etc., which are chimerical. It is the easiest to perform if the operator will bear in mind the technique. The lower bowel to be emptied by enemata, the pubes shaved, the patient anesthetized, the bladder washed out by solution of boric acid. It is best done by a bag suspended, say three feet, above and the solution allowed to escape after the bladder is full: repeat till the escaping fluid is clear. The bladder is then filled and an assistant retains the catheter and washing apparatus so that when the fluid escapes by the suprapubic opening more enters by the catheter. Place the patient in the Trendelenburg position. Stand on the left side of the patient, incise in the middle line from a point half an inch below the upper border of the symphysis to a point two and a half inches above the pubes. Cut through the skin and fascia, exposing the muscular aponeurosis. The finger now feels in the lower part of the incision for the notch marking the upper border of the symphysis. Here boldly thrust in the knife till its point is arrested by the cartilaginous junction of the pubic bones. Expose this early; it is easy to find, and the incision may be carried down to it with a disregard of the abdominal contents. It is the principal landmark, as it marks both the lower limit but divides the muscular aponeurosis and separates the tendinous insertion of the muscles. Divide the aponeurosis the length of the wound, separate the recti with the handle of the scalpel. Use retractors to separate the margins of the wound. Right index finger should be inserted at the lower angle, hugging closely the inner surface of the pubic bones. In sixteen operations he followed this plan, not regarding the peritoneum. As the finger approaches the lower border of the symphysis it lies in contact with the anterior surface of the bladder, at this point covered with fatty tissue and a plexus of veins. The fluctuating bladder is distinctly felt. If in doubt, an assistant should pass a finger into the rectum and press forward and thus determine its position. The bladder wall is then fixed by thrusting two tenacula through its most prominent part. A narrow bladed knife is thrust cutting edge up, into the bladder between the tenacula and the incision carried down to any desired extent, to be determined by the nature of the case and requirements for intravesical manipulation. While the bladder is open it should be continually flushed with the boric acid solution to keep it and the wound clean and the field free from blood. Suturing the bladder has long been debatable. If there is a marked cystitis with putrid urine, the incision is not likely to heal save by granulation. The advantage of primary union is so great that an effort should be made to obtain it except where septic condi-

⁸ See my paper on "Phenacetin as a Toxic Agent" in Transactions of Texas State Medical Association, 1895; also in JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, May 11, 1895.

⁹ Deutsche Med. Wochenschrift, No. 14, 1895.

tions are such as to preclude its possibility, or in cases where the limited extent of the incision, aided by the retention of a catheter in the urethra, renders suture of the vesical walls unnecessary. The upper and lower angles of the wound in the abdominal wall should be sutured and a pledget of iodoform gauze loosely inserted into the prevesical space and the ordinary dressings for a laparotomy applied. Retain the catheter in the urethra and drain the bladder for several days.

DR. CARL SEILER, of Philadelphia, read a paper on "Perforation of the Nasal Septum."

DR. EVAN O. KANE, of Kane, read a paper

THE CHIEF PREDISPOSING INFLUENCE IN THE PRODUCTION OF TUBERCULOSIS.

While paying the highest respect to the tubercle bacillus as a determining factor in the production of tuberculosis, he pointed out certain contradictory and puzzling phenomena which confront the practical physician in his endeavor to apply the theory. He placed considerably greater stress upon the importance of certain vague preëxisting phenomena than scientists have lately appeared to. Next he endeavors to describe these phenomena pointing out that they are not due as has hitherto been supposed, to certain unhygienic conditions but are due to a diathesis which while strumous is actually the result of an inherited syphilitic taint much attenuated often, yet still of a grave character. He further shows how such a diathesis is specially adapted for the reception of the tubercle bacillus and for the production of tuberculosis. The article closes after having proven how important a part the inherited taint plays, by an appeal to physicians not to overlook so grave a predisposing influence in their endeavor to eradicate a germ whose position would be untenable without it.

DR. MARY MCKAY WENCK, of Sunbury, read a paper on "The Hygiene of Pregnancy."

DR. W. H. HARRISON, resident physician of the Insane Asylum at Harrisburg, gave a paper

THE PATHOLOGY OF THE BLOOD OF THE INSANE.

Insanity is a disease of the physical system. Owing to our ignorance of the minute structure of the encephalon and its physiology and pathology, the principles of psychology and psychiatry are arranged still on functional lines. The tendency of the times is to develop the principles that every function has a physical center and that every derangement of function is due to morbid change of such physical center or else to some pathologic interference with its relations to certain parts. Acute insanity is always associated with derangement of one or more parts of the physical system. Examination of the dejecta and secretions often makes this plain enough. The exterior of the body shows symptoms of widespread disease which the experienced alienist makes note of. Disturbance of the mind is only too commonly accompanied by disturbance of the digestive functions. Careful analysis of the urine of over five hundred cases of insanity reveals pathologic changes in this fluid in a large proportion of cases. In all forms of insanity there is physical waste as well as deterioration in the acute stage, and in the chronic condition as well, though such change is modified to some degree in the latter by an improvement in the physical condition at the close of the acute period. Pathologic changes in the blood are some of the physical symptoms of the mental disorder, primarily or secondarily. There is a tendency to very slow coagulation after withdrawal of the blood in many cases although in the acute insane the tendency to clot early is quite pronounced in some cases. We have noticed this tendency where there is increase of specific gravity of the blood as a whole, where there is concentration of the blood from liquid abstinence. The specific gravity as a whole is commensurate with its physical condition. In exaltation when the number of cellular elements is above normal exceptionally the specific gravity is likewise above normal. By means of the hemoglobinometer, hemocytometer, hematokrit, we learn very important symptoms, which the customary means at the hands of the physician do not reveal to us. We thus learn by more scientific means the physical state of the individual. And so we have come to take blood data of each individual on his entering the hospital and in special cases at certain intervals. We are thus guided in our dietary and medical and hygienic treatment of the insane. The blood of the insane is impaired or in a morbid state. In mania the rule is that the red cells are diminished in number, the diminution corresponding to the deterioration of physical health generally. But in many maniacs near the inception of the exaltation, especially where the period of depression has been short and the disease has not had time to cause palpable physical deterioration, such exaltation is sometimes accompanied by an increase of the red cells above the normal. The secretions and

the emunctories act powerfully and rapidly so that there is rapid drain of water from the system, which loss of fluid is seen in the blood in a very short time, and consequently there is increase of hemoglobin and of red and white cells and plaques in proportion. We exceptionally meet cases where this proportion is distinctly modified, the white cells and plaques, more rarely either alone, being in greater or less proportion to the red cells than normal. At the same time the body weight declines. Thence the propriety of supplying the maniac with abundant food and drink at frequent intervals, with tonic remedies. In an exhausted maniac who came within our notice a few months ago the number of red cells per cu. mm. was about 8,000,000. After a liberal supply of food and fluid at the end of ten hours there was a reduction of red cells to 4,000,000. As to the hemoglobin we have only very rarely found it increased above normal in mania. Although diminished below normal in mania, as the rule it is at greater degree in exaltation than in depression. As a rule, the ratio of white cells and plaques bear the same relation to the red cells as in health. However, there are many variations as to these bodies with the physical deterioration in different forms of depression. In melancholia there is notably a diminution in red cells, with exceptional cases. The profounder the depression the more pronounced such diminution. And yet at Kirkbride's Hospital we examined the blood of patients who were regularly fed by tube for long periods and in whom the reduction of red cells was only slight. As in exaltation so in mania there is often considerable variation as to the ratio of white cells and the plaques to the red. In dementia the diminution of red cells and white cells and plaques in proportion is commonly quite marked. In the case of a dement at Kirkbride's the number of red cells was as low as 918,000. In some cases of dementia, however, at the State Hospital we have found that the diminution was only slight, cases of men and women who, after the storm of mania and melancholia has passed and the body took on flesh, increased in weight and became well nourished, and the white cells and plaques were in normal proportion, and the hemoglobin though below normal was of a pretty fair figure. In dementia we frequently find a disproportion of red to white cells and the plaques more commonly than in acute insanity. In epileptics we sometimes find excess of the cellular elements beyond the normal line during and immediately following convulsions, at all events in many cases a decided increase, and the hemoglobin increased, with many corresponding physical symptoms, as the appearance of albumin in the urine, all due to great functional disturbance, and after some hours a corresponding diminution in these elements, notably below the normal line, a true reaction after the violence of the convulsions, and later on the more equable deterioration of many physical symptoms including those of the blood as in dementia. In paretics likewise during and immediately following the convulsion there is commonly an increase in the cell elements, sometimes beyond the normal line, to be followed after some hours by the reactionary diminution of the cells and hemoglobin, and then later on the steady decline in cells as to number and in the hemoglobin which decline is very rapid, keeping pace with the general physical deterioration in many other respects.

DR. ANNA M. FULLERTON, Philadelphia, read a paper "Records of Work in the Woman's Hospital of Philadelphia." She gave a summary of the work done from 1886 to 1896, demonstrated the comparative frequency with which the various forms of pelvic disorders occurred. Inflammatory complications of septic origin, puerperal or gonorrheal, were found to constitute a very large proportion of the conditions treated, which to the author's view, explained the necessity for so frequent a recourse to medical rather than palliative measures in their management. Cases were cited from the records of the author's work in the hospital illustrative of this point.

DR. W. C. HOLLOPETER, of Philadelphia, read a paper on "Milk Filtration."

On motion of Dr. John Curwen, of Warren Insane Asylum, a committee of five was appointed to memorialize the legislature in favor of the establishment of a hospital for the acute, chronic, convalescent and epileptic insane of the counties of Potter, Tioga, Clinton, Lycoming, Clearfield, Jefferson, Center, Huntingdon, Blair, Cambria, Bedford, Somerset and Indiana.

On motion of Dr. A. Koenig, of Pittsburg, it was resolved:

WHEREAS, a large number of physicians and surgeons are engaged in valuable and gratuitous service in the State of Pennsylvania; and

WHEREAS, such physicians and surgeons are conspicuously familiar with the interests and requirements of the hospitals with which they are connected;

Resolved, That it is the sentiment of this Society that every

hospital having an unsalaried staff should have in its Board of Managers a liberal representation from its medical and surgical staff.

THIRD DAY—MAY 21.

DR. GEORGE E. SHOEMAKER, of Philadelphia, read a paper,
THE FIBROID UTERUS: WHEN AND HOW TO OPERATE.

Improvements in technique in the last five years have lessened the primary mortality; have lessened complications and have increased the number of patients who should be subjected to operation. Small tumors call for extirpation when severe bleeding and pain resist minor measures and this should be done before the patient is exhausted. Awaiting the menopause often disappoints expectations of relief. All large growths, all associated with septic inflammation, all which are rapidly growing, all which are likely to obstruct labor call for removal. Where the tumor prevents recovery from severe types of functional nerve disorder or in incipient phthisis, it may be removed. The presence of heart and kidney lesions, if not too severe, call for more careful preparation and management, including frequently the early supply of liquid nourishment by the bowel after the operation. Removal of the tumor may relieve the kidneys where ureteral obstruction and interference with bladder drainage has caused nephritis. As to the method of operating the writer objects to removing the tubes and ovaries as frequently difficult and dangerous or ineffectual. He has tried several methods of hysterectomy, but considers ligation, with amputation through an abdominal incision at the internal os, followed by dropping the stump and closing the peritoneum over it, to be the method of election; yet, other plans may be followed to meet individual indications.

DR. WALTER H. PARCELS, Lewiston, read a paper,
OBSCURE TRAUMATIC LESIONS OF THE ENCEPHALON.

He called attention to the fact that in all head injuries the surgeon finds it difficult to make a prompt diagnosis of the amount of injury the encephalon had received. The prognosis should be guarded and he exemplified these statements by three cases in his practice. One from an apparent fracture at the base of the skull, recovery; another where the injury seemed slight, but death occurred in thirteen hours. Post-mortem showed no fracture, a rupture of blood vessels of pia mater, large blood clot with compression of brain. The third, a fall upon the forehead, concussion of brain, no fracture believed to exist, but unconsciousness, a chill and excessively high temperature following the third day and death three days later. No post-mortem. What was the correct diagnosis? Was there a spicula of bone that had caused a lesion of the membrane and possibly a lesion of the cortical substance and acute meningitis? Wherein as a surgeon did he fail to do his duty in this case? The recognized surgical treatment is not fully detailed for the reason that we are waiting the revolution to be inaugurated by the perfection of the X rays, when a cathodic photograph will enable us to make a correct diagnosis and the trephine and suction pump will be the instruments used for spicule of bone and intracranial blood clots.

DR. J. W. PARK, Dauphin, read a paper,

THE MEDICO-LEGAL ASPECT OF EYE AND EAR CASES.

He confined his paper to accidental injuries. The points of interest were the kind of an examination, record of the case that should be made at the time, the kind of cases which should be examined by a specialist, the requirements of the general physician and specialist in medico-legal cases and their advantage to the plaintiff and defendant in suits for damages. He cited a case. He was sent by a road to examine the eyes of Mrs. S., who one year and three months before had been in a wreck and claimed that her present defective sight was due to the injuries. A careful examination of the fundus of each eye revealed dense opacity in the vitreous humor of both eyes, and no good view could be obtained; it was evidently a case of disseminated choroiditis. Hemorrhages into the vitreous may cause this, and this she claimed to be due to the blow received as the car turned over. The attending physician had not made an ophthalmoscopic examination, hence could not say how it looked, whether any hemorrhage were present. This was fatal to the road. All accidents involving the eyeball, cornea, lens, iris, fractures of the orbit or where vision may be impaired from intra or extra ocular injuries or diseases and in all cases where there are hemorrhage from the ears or signs of fracture of the skull involving the ear, where a careful examination for any previous existing deafness should be made and a minute record kept, in all these the physician should have in consultation a specialist. This should be immediately done for the benefit of the patient and for any legal complication that may arise. Take nothing for granted. In another case I am confident the

deafness was due to a chronic catarrhal otitis media that had existed for years; but thousands of dollars were paid to settle. A third case of severe neuralgia of the superior maxillary nerve was sent to me by an attorney, claimed damages for the street crossings not being clear of ice, causing a fall, crushing in the malar bone and thus injuring the nerve and causing a chronic neuritis of the superior maxillary with pain in the ophthalmic branch. It had not in the least affected his vision. This was two years after the fall. He wanted me to discover something wrong so as to claim damages. No record was kept and no definite testimony was obtained. Let us try at least to show professional skill so that we may appear as experts and not figure heads. The requirements in a court of law are so numerous and complicated that I can refer to but a few. First, you should thoroughly understand the anatomy and physiology of the eye and ear, so as to answer questions relative to them in cases of injuries. Be familiar with the use of the ophthalmoscope; differentiate a diseased eye from a well one. Know the appearance of interstitial keratitis and that it is only syphilis, hereditary or acquired, that it will produce a peculiar condition of the cornea. You should know how to treat and save from blindness. Always state the probable results; make no promises of recoveries or length of time needed. In ear cases, be able to detect a simulating deafness from a real one. A teacher strikes a child with the flat of the hand; the parent takes it to a physician; he finds a ruptured drum. You may be asked how you know that it is not an old perforation. Traumatic perforations have traces of blood fresh or dried near the edges of the wound and in using inflation of the ear the air passes out easily into the auditory canal, while in pathologic perforations the exit is only under pressure and produces a whistling. In rupture from compressed air the rupture usually occurs at the periphery of the membrane, but in rupture from fracture of the bone as by blows, etc., it occurs in any part. This is accounted for as follows and is important in a medico-legal view. The drum membrane is generally contracted toward its center by the oto-muscular apparatus and often favored by chronic hyperplastic forms of catarrh, atrophy and cicatrices near the drum head, making this its weakest point where the rupture most always occurs. The ear must be carefully examined after injuries. An employe may claim damages for loss of hearing, claiming it from a blow on the ear, when really due to impacted cerumen. In one case I removed a lot of impacted cerumen and two dead bugs; hearing became normal and he never claimed damages after that. Precautionary measures, records, etc., apply equally to diseases as well as injuries of the ear. On the witness stand answer all questions clearly in plain terms. Illustrate by models so the jury can understand. In all cases make a thorough examination, keep a record in detail. If not capable of using the ophthalmoscope or ear speculum with reflected light, have a consultation and at once. Be well versed in the anatomy and physiology of the eye and ear; study both in health and disease; try to have much experience as without all this you had better not approach the witness stand. Always get the consent of the proper authorities before performing any operations; never promise any definite results or time.

DR. EDWIN ROSENTHAL, of Philadelphia, read a paper,

THE REDUCTION OF THE PERIOD OF INTUBATION BY SERUM TREATMENT OF LARYNGEAL DIPHTHERIA.

Dr. Rosenthal exhibited to the meeting the various strength, of antitoxic serum (the "Standard" 100 units to each c.c.; the "Potent" 250 units to each c.c.; and the "Extra Potent" 500 units to each c.c., of the H. K. Mulford Company's make) used by him at the present time in the treatment of those cases of diphtheria embodied in the present paper. Dr. Rosenthal also showed the culture tubes provided by the Board of Health, along with the cards giving the results of the bacteriologic examinations, made by the bacteriologic department of the Philadelphia Board of Health. He then in a series of admirably arranged comparative and statistic studies on the subject of intubation seeks to prove:

1. That the operation of intubation is the most desirable and more favorable than tracheotomy.
2. That with the serum treatment of diphtheria, tracheotomy will no longer be necessary.
3. That the serum treatment in diphtheria exerts a most marked and favorable reduction in the time the tube is worn in the larynx.

Pre-Serum Period, American. In a series of cases occurring in Dr. Rosenthal's practice there were 38 recoveries in 100 cases, and a mortality of 62 per cent. The tube was worn in 12 cases, 46 to 96 hours, mortality 31.40 per cent.; in 26 cases, 120 to 672 hours, mortality 68.60 per cent.; minimum duration 48 hours; maximum 672 hours; average time tube was worn

185¼ hours. Dillon Brown (June and July, 1887) places the time for final extubation at 5 days 3½ hours—that is, 123½ hours. O'Dwyer in 158 recoveries gives the average as 6 days, 2 or 3 hours (146 to 147 hours). Louis Fischer reports to the writer, 4 cases, 50 to 60 hours, 25 per cent.; 12 cases, 148 to 624 hours, 75 per cent.; minimum duration 50 hours; maximum 624 hours; average time 176½ hours.

Pre-Serum Treatment, European. Gustave Baer performed final extubation at the Zurich Children's Hospital as follows: 20 cases, 1 to 5 days, mortality 64.50 per cent.; 11 cases, 6 to 52 days, mortality 35.5 per cent. Prof. Von Ranke gives: Within 24 hours with a mortality of 8 per cent.; within 48 hours, 26 per cent.; within 72 hours, 18.50 per cent.; within 96 hours, 20 per cent.; over 96 hours, 27.50 per cent. Huebner in 25 cases of recovery has given 100 hours as an average when final extubation could be performed. Johann Bokai (Stephanie Kinder-hospital, Buda Pesth) reports 673 cases of intubation, of which 223 (33½ per cent.) were cured; of these 223 cases, 8 were tracheotomized, if we subtract these we have 215 cases. From ½ to 120 hours, 82.33 per cent.; from 120 to 240 hours, and 7 cases over 7 days, 17.67 per cent., showing a minimum of ¼ to 9 hours; maximum of 217 to 368 hours, average duration 79 hours.

Post-Serum Period, European. Huebner reports ten cases of intubation in diphtheria treated with antitoxin, with an average duration of 37 hours. In Von Ranke's cases the tube was removed within 24 hours in 18 cases, 18.5 per cent.; within 48 hours in 48 cases, 48.1 per cent.; within 72 hours in 11 cases, 11.1 per cent.; within 96 hours in 10 cases, 10 per cent.; over 96 hours in 3 cases, 3.7 per cent. Of 90 cases intubated by Bokai since the serum period, 45 recovered, 50 per cent. In this group of cases the minimum was 1 to 7 hours; the maximum 150 to 160 hours. To show the comparison between the two periods before and after serum treatment Bokai tabulates his cases. His table shows that the number in the 1st and 2nd 24 hours has conspicuously increased; the average being 61 hours against 79 hours before the serum period, therefore the serum period has lowered the duration of intubation 18 hours.

Post-Serum Period, American. O'Dwyer intubated 30 cases since the period of serum treatment of which 20 recovered, 66 per cent. The duration of 19 of these cases was from 8 to 119 hours 17 cases, 89½ per cent.; 120 hours, 2 cases 10½ per cent. Minimum, 8 hours; maximum, 120 hours; average, 83½ hours, as against 147 hours previous to antitoxin treatment. Therefore the serum treatment has lessened the time of incubation 63½ hours. Dr. O'Dwyer has informed the writer that the average duration of intubation has been 80 hours, making his reduction 67 hours. Louis Fischer reports 30 cases of recoveries after intubation: 19 cases, 16 to 116 hours, 63½ per cent.; 11 cases, 128 to 408 hours, 36⅔ per cent; minimum 16 hours; maximum 408 hours.

To show the comparison between the two periods before and after serum treatment, Dr. Rosenthal tabulates Fischer's cases similarly to those of Bokai, with the resulting summary. Before antitoxin: Percentage of cures before 120 hours, 25 per cent.; percentage of cures after 120 hours, 75 per cent. After antitoxin: Percentage of cures before 120 hours, 63½ per cent.; percentage of cures after 120 hours, 36⅔ per cent. This table shows that in the first three days the percentage of recovery has increased. The average number of hours in the pre-antitoxin period was 176½ hours. Post-antitoxin period was 108¼ hours, a reduction of 68 hours in the time the tube was worn. Dr. Rosenthal gives the result of 20 cases in his own practice: of these cases two died, 10 per cent. In those cases that recovered the duration of intubation was as follows: 12 cases, 12 to 103 hours, 66⅔ per cent; 6 cases, 146 to 291 hours, 33⅓ per cent. Average number of hours tube was worn, 114 1-6 hours. Compared with time pre-serum period, 185¼ hours, shows a reduction of 71 1-12 hours. Tabulated as in Bokai's cases: Pre-serum period, before 120 hours, 47.5 per cent.; after 120 hours, 52.5 per cent. Post-serum period, before 120 hours, 66⅔ per cent.; after 120 hours, 33⅓ per cent. In the operation of tracheotomy the writer has had no personal experience, but quotes E. Kohl, who gives the results of a study of 800 cases of recovery, and the difficulty he assumes to be when the final decanulement can not take place after three weeks. There were in 24 cases final removal in 3 days; 71 cases final removal in 4 days; 94 cases final removal in 5 days; 30 cases final removal in 6 to 10 days; 200 cases final removal in 10 to 30 days; 50 cases canula was worn 1 to 12 months. Bokai's experience in tracheotomy follows: In the majority of his cases (84 per cent.) he was enabled to withdraw the tube within 10 days, on the 6th or 7th day, 44½ per cent.; in 5 days, 23½ per cent. Kohl's and Bokai's cases placed in comparison give (tracheotomy per cent. of recoveries) Kohl, under 5 days, 23½ per

cent.; 5 to 10 days, 37½ per cent.; over 10 days, 38⅔ per cent. Bokai, under 5 days, 23½ per cent.; 5 to 10 days, 60½ per cent.; over 10 days, 16 per cent. Intubation per cent. of recoveries: Bokai, under 5 days, 83.08 per cent.; 5 to 10 days, 16.02 per cent. O'Dwyer, under 5 days, 89.51 per cent.; 5 to 10 days, 10½ per cent. Fischer's, under 5 days, 63½ per cent.; 5 to 10 days, 16⅔ per cent.; over 10 days, 20 per cent. Rosenthal, under 5 days, 66⅔ per cent.; 5 to 10 days 22 2-9 per cent.; over 10 days, 11 1-9 per cent. Bokai's cases show the average duration of intubation to be 79.6 hours, and in the majority of his cases (83.08 per cent.) final extubation was performed within 5 days (120 hours) even though a relatively large number in 217 cases, 42 cases, 16.02 per cent. were intubated over 5 days, without the longer intubation being in any way dangerous. Under the serum treatment no alarming symptoms (decubitus, etc.) were manifested: for that reason but one conclusion can be borne, that the operation of intubation is alone sufficient, and the secondary operation of tracheotomy can be avoided. O'Dwyer's cases show the average duration of intubation to be about 80 hours, and in almost all his cases final extubation was performed within five days. Dr. Rosenthal quotes from a letter received from Dr. O'Dwyer, which most forcibly demonstrates the utility of the serum treatment: "My results up to the present time in 500 cases in a series of hundreds: First hundred (largely experimental), 17 recoveries; second hundred, 27 recoveries; third hundred, 30 recoveries; fourth hundred, 26 recoveries; fifth hundred, 39 recoveries. The marked increase in the last series was due to antitoxin, in thirty cases of which there were 20 recoveries. In the 70 preceding cases in which no antitoxin was used there were only 19 recoveries, which was about the same percentage as in all the other series."

O'Dwyer's statistics therefore substantiate Dr. Rosenthal's. From a mortality ranging from 83 per cent. to 70 per cent. before the serum period, his reduction has been to 30 per cent., and the reduction in the time the tube was worn was 67 hours. Fischer's cases show the same characteristics as in O'Dwyer's cases and Dr. Rosenthal's, the average duration of intubation was 108¼ hours and in 63⅔ per cent. final extubation was performed within 120 hours. In one of Fischer's cases seen with Prof. H. J. Boldt, intubation and extubation was performed five different times during a period of 408 hours, which has somewhat raised his average. However, the reduction in the time the tube was worn is equal to O'Dwyer's and Dr. Rosenthal's, and averages 68 1-10 hours. The relatively large numbers (in 30 cases, 11 cases, 36⅔) were intubated over five days (120 hours). No dangerous symptoms arose necessitating tracheotomy. Intubation with the serum treatment has been sufficient in Fischer's hands to perform the cure. Dr. Rosenthal's own series of cases show the average duration of intubation with serum treatment to be 114 1-6 hours, and in the majority of the cases (12) final extubation was performed within 5 days. In his long cases he has never seen any indications that would call for tracheotomy, and in one of his cases, intubation and extubation were performed very frequently with favorable results. In his paper Dr. Rosenthal refrains from mentioning those cases of laryngeal diphtheria treated with antitoxin, which recovered without the aid of intubation. These cases were in a greater number than those operated upon, and the reason unquestionably has been due to the early use of antitoxin.

The writer's conclusions after using the serum treatment in the last eighteen months are as follows: "1. The duration of intubation varies. In the cases quoted extubation has been made in from ½ to 408 hours. The rule, however, in the majority of cases is that final extubation can be performed within 120 hours. 2. The average length of intubation has been reduced in a marked degree: Bokai, 18 hours; Von Ranke, 25½ hours; O'Dwyer, 67 hours; Fischer, 68 1-20 hours; Rosenthal, 71 1-6 hours. 3. The operation of tracheotomy is avoided, intubation being sufficient to cure, even in the long cases, 5 days and over, there were no symptoms necessitating such procedure. 4. The use of the serum has placed intubation on a definite basis: (a) by lowering the mortality; (b) by shortening the period of intubation; (c) by avoiding the major operation, tracheotomy."

THE PRESIDENT—The paper of Dr. Rosenthal is open for discussion.

DR. NOBLE—I would like to hear from Dr. Welsh in the discussion of this paper.

DR. WELSH, of Philadelphia—I did not intend to take part in this discussion, but I am obliged to say that my experience is not in accord with the author of the paper. He contends in the paper that the tube may be removed much earlier when antitoxin is used than when it is not. He does not know that in order to determine that fact it is necessary very frequent

experiments should be made every day in removing the tube, both in the non-antitoxin cases and in the antitoxin cases, to the earliest period of the disease when the patient can get along without the tube. Now, no such experiment has been made. Before the introduction of antitoxin, we were told that it was necessary that the tube should remain in for six, seven or eight days. O'Dwyer's instructions are that the tube may be removed on the seventh day. Now, I think that was pretty generally followed before the introduction of antitoxin. So it is not known just how long a patient can get along without a tube. That can only be ascertained by removing the tube and learning. Now, since antitoxin has come into practical use, some writers claim that the patient can get along earlier without the tube; and they have found by experiment that in some cases they get along without. So I say that this conclusion is scarcely warranted, unless experiment is made of the two cases precisely in the same way. I have tried removing the tube at an earlier period of the disease; but have found that we had to introduce the tube again repeatedly. We first thought that we could get along without the tube after having worn it four days, with the use of the antitoxin; but we found that we had often to hasten to get the tube back, and save the child's life. A patient in one of the wards of a hospital in the city of Philadelphia wore a tube three months. During the three months the tube was removed or coughed up as often as seventy times; and yet it was impossible to get along without it. The child would often run into the sleeping room of the resident physician, with its night clothes on, having coughed it out and carrying it in its hand. The physician would reintroduce the tube and the child would go back to bed. I have seen the child and I am sure it would not have lived fifteen minutes if the tube has not been reintroduced, and, as I stated, that child was required to wear that tube three months. Frequently the tube has to be used as long as three weeks, even where the antitoxin is used. Not very long ago a patient was sent to the hospital, having received antitoxin before its introduction, a number of hours later. I do not think it was as long as twenty-four hours after that intubation was necessary. It was found to give a temporary relief. The child was then sent to the hospital in that condition. It continued to use the tube; in six days we thought we would remove it and did so. Serious symptoms at once developed, and the tube was reintroduced, and the child wore the tube four days longer. We thought then we could remove the tube and did so. The resident physician told me he had to hurry with all the haste possible from some other part of the institution in order to put the tube back and save the child. One morning, about the eleventh day, at 5 o'clock, the child coughed up the tube. Its condition at once became serious and the nurse telephoned over to the other building for the resident physician. Before he got there that child was dead. It was an antitoxin case. I have very frequently met with cases where the tube is coughed up and the child gets along very well, no matter whether the child has taken the antitoxin or not. I have frequently had children do pretty well after the tube was introduced and taken out immediately. They breathed better for a time.

Dr. T. D. DAVIS, of Pittsburgh—I have had considerable experience personally in the use of antitoxin. We make it in Pittsburgh ourselves and we know it is good. We know its strength and we know the results. At the last meeting of the Allegheny County Medical Society the subject was up before the members. There was not one single remark made by any doctor present derogatory to its great efficiency. Some of the cases reported were a little short of miraculous. In my own personal practice I have seen two cases where, as it were, the child was snatched as "a brand from the burning" by its use. There are various ways of using it. Because a man says a case has been treated with antitoxin and dies it does not follow, therefore that antitoxin was of no value or that it could not have been made of greater use in that individual case. A great deal depends on how it is used, the quality and quantity used and the time of use. If you have a patient suffering with malaria and give one small dose of quinin, you treat the patient with quinin, but how? The same applies to the treatment of diphtheria with antitoxin. If you administer 500 units when it requires 5,000 units to neutralize the poisons, your patient will die: not on account of the antitoxin but because you have not given a sufficient amount. If our theory in regard to the serum is correct it is one of the few remedies that is beneficial whether it does any good to the diphtheria or not. It not only is harmless but it is beneficial. You are putting food into the body. You can not possibly cause injury by it, if it is pure and good. You absolutely benefit, in the same way as you would by injecting milk or beef tea. Therefore you are not using a dangerous remedy. In one of the cases reported

at the Allegheny County Society, 142 cubic centimeters were used in the case of a child 7 years of age, within thirty-six hours, with a recovery. Antitoxin does not propose to remove spasm of the larynx, nor reduce congestion or an inflamed condition. Antitoxin proposes to remove the diphtheria and not its results. I know when I use it, when the membranes have disappeared. I am thus free to say whether the tube can be removed or not. I know that I have never seen a case, by the use of antitoxin, that lasted over forty-eight hours. Now, if this membrane was in the larynx and the intubation was used solely on account of the membrane, then I would take it away. If there was spasm of the larynx and congestion remained, then such would have to be treated. The antitoxin would have no effect on such a case, as it only cures the diphtheria.

Dr. ROSENTHAL—The expression made by my colleague from Pittsburgh is exactly what I wished to make: While antitoxin is a specific for diphtheria, you must know how to use it. If you give one administration the child may not recover; I have seen recoveries in laryngeal diphtheria that were intubated in almost hopeless cases. Therefore I am ready to stand by the antitoxin and to go down with the antitoxin. While it is of signal importance to employ antitoxin as early as possible, I never despair, even when called late, but in such cases give larger amounts of antitoxin, 2,000 units as a commencing dose.

The antitoxin which I have exhibited here is presented in three grades of strength. Let physicians use it as I have told them, and if there are any failures let them be attributed to me. I do not know about the Philadelphia Municipal Hospital, but it stands unique in regard to its mortality list, which is the greatest in the world to-day, and is the only institution that has not reduced its mortality since the introduction of antitoxin. I have presented a number of cases where my conclusions are proven and if the opportunity were offered I could demonstrate the same at the Philadelphia Municipal Hospital. I have daily reports made with analysis of urine, etc.; in no case has albuminuria been noted, and I have not noted any joint pains, and in but few instances a slight urticaria, which soon disappeared, and which I have noted in cases treated by me before the serum period. Dr. J. S. Billings, Jr., has reported in the *Medical Record*, April 25, that the "antitoxin treatment has no deleterious effects upon the blood corpuscles. On the contrary, it seems to prevent degenerative changes which would otherwise be brought about. A knowledge of the duration of the period of intubation ought to have some value. When I inject the antitoxin in insufficient quantity, and ascertain the result, I repeat with an increased number of units, and when the symptoms are favorable I take the tube out. In one case it remained 148 hours, but it was not due to antitoxin. I do not like figures that are incorrect, and long to have them right. When you have used antitoxin and on the second day the temperature rises again it is an indication of insufficient antitoxin having been given, and indicates the further need of antitoxin, and I give it in double or treble amounts; if my first injection was 1,000 units I administer 2,000 units, and if the third injection is necessary, 3,000 units. To use antitoxin for other complications, you may as well expect to give a dose quinin, with beneficial results, when a man has abscess of the liver. But antitoxin will cure diphtheria, and I know that it decreases the mortality, and that it reduces the time for the tube to be worn. Dr. Fischer and Dr. O'Dwyer, of New York, the originator of the tubes which I have shown, will stand by the same thing.

Dr. W. B. ULRICH—Before the Doctor takes his seat I would like to have this question answered by him and Dr. Welsh: Have you ever known any harmful results from the use of antitoxin? I, myself, would not feel with my experience in its use, that I had done my duty in not using antitoxin in diphtheria, notwithstanding my skeptical views when antitoxin was first introduced. I would like to have this question answered before the society.

Dr. ROSENTHAL—I have used as high as 13,000 units in one case with curative results.

Dr. ULRICH—Have you had any harmful results?

Dr. ROSENTHAL No, sir. Neither have I found any by examination of the urine. There is a difference in the injection, depending upon the kind of antitoxin you use. If you use Gibier's antitoxin you can use enormous amounts with scarcely any effect.

Dr. W. B. ULRICH—What kind of antitoxic serum do you use?

Dr. ROSENTHAL—I use Mulford's exclusively in my practice. Of the Mulford product you can secure three different strengths. The "Standard," containing 100 units to each c.c., the "Potent," containing 250 units to each c.c., and the "Extra Potent," containing 500 units to each c.c. Each of these strengths being supplied in vials of 500, 1,000 and 2,000

units. The charts I have shown the society were treated with the "Potent" and "Extra Potent." In one case the tube was withdrawn within seventy hours, and the child was cured; in the other case within seventy-three hours, with like results. I have never seen a single unfavorable symptom where Mulford's antitoxin was used, and I now use it exclusively, as it has given me more prompt results than any antitoxin I have ever employed.

DR. WELSH—I have never seen any fatal results; but I have seen some complications arising from urticaria and joint pains.

DR. W. M. BEACH, of Pittsburg, read a paper,

SPECIAL FORMS OF RECTAL FISTULÆ.

Only within the last decade has there been any considerable enthusiasm evinced by the medical profession in the study of rectal diseases. Now every important city has one or more reputable physicians interested in this line of work, thereby adding to the list of legitimate specialties. I do not attempt any originality, but rather to arouse your interest in a field of research much neglected and relegated to quackery. It is generally conceded that next to hemorrhoids, rectal fistulæ most frequently claim the attention of the rectal specialist. Though the pathology of fistula in ano is familiar to all, and the subject trite, it is the purpose to direct attention to "special forms" and the surgical procedure toward a cure. Fistulæ with surface openings will receive no consideration, but rather the blind internal fistula with a rectal orifice and those connecting two cavities. Two reasons obtain for presenting these forms: 1, the frequent obscurity of symptoms and lesion; 2, the difficulty in obliterating the abnormal canal. Many an obscure case of pelvic disease will stand out in clear light through a skillful exploration of the rectum. The uterus and appendages, or posterior urethra, frequently bear the onus of some disease of the rectum, trifling or otherwise, and a failure to cure inevitably ensues. The internal blind, or the recto-perineal blind fistulæ are chiefly found in the anterior wall of rectum, though the submucous variety may occur in any portion, and the opening, usually small, is found in a pocket just above the internal sphincter. Periodically, induration may occur on the surface, which is an aid in locating the sinus, that can be traced downward and forward with a bent probe. This condition is not rare, but often overlooked. The recto-urethral, or recto-vaginal fistula, is the second form I wish to present, and is easy of diagnosis but difficult to cure, the former being the reverse. The subjective symptoms are certain in the latter for the most part, and leave no doubt in the mind of the physician. The science of obstetrics in its evolution plays no small part as an etiologic factor. The middle of the dying century tolerated a practice of non-interference in the conduct of confinement resulting in anterior vaginal fistulæ the result of sloughing tissues from prolonged pressure of the fetus in the parturient canal. Latterly an opposite extreme obtains; the too frequent, not to say unskillful, application of traction instruments produce extensive perineal lacerations, often obliterating the recto-vaginal body attended with paralysis of the sphincter, and the traumatism may mark the beginning of a recto-vaginal fistula. Lithotomy is not without its danger in producing rectal fistulæ, and may be mentioned as an important factor. Thrusting the knife through the membranous urethra, the rectum may be punctured, leading to a permanent tract. This accident was probably more frequent prior to the use of anesthetics, agents so conducive to calm deliberation in surgical manipulation. Abscess is by far the most frequent source of rectal fistulæ: in fact, most authors believe it to be a *sine qua non* in their production. Perirectal abscess may arise from a constitutional diathesis, or a traumatism surgical or otherwise. The point of least resistance is usually toward the rectal cavity, becoming a blind internal fistula. The following illustrative case came under my observation: L. S., aged 35, occupation merchant, family history good, applied to me for the relief of some obscure rectal trouble. He had considerable urethral irritation for which he had been treated over a year, his physician supposing it to be of gonorrheal origin, doubting the emphatic denials of his patient. Careful questioning revealed the fact that shortly before his trouble he had fallen astride some wares in the basement of his store, followed in a few days by pain, heat and swelling in the perineum, which suddenly subsided on the appearance of a rectal and urethral discharge, the latter more profuse. At this stage he consulted another physician, who faithfully treated the supposed gonorrheal discharge, which soon stopped. Pain in back and hips and a rectal discharge still persisted, but he was assured that the rectum was healthy, the symptoms being a result of the past urethral catarrh. He came to me much discouraged. By aid of a speculum and an electric lamp, a thorough search was made of the lower three

inches of the rectum. I found nothing pathologic. A third trial about two weeks afterward was also likely to prove futile, but when about to withdraw the speculum, I made a pressure on the perineum, which forced purulent fluid through a minute orifice on the anterior wall of the rectum. A bent probe entering this brought the exclamation: "You have touched the spot, Doctor," and the instrument passed into a large cavity as deep as the urethra, as was subsequently demonstrated by the operation, which consisted of free incision and dissection. The patient fully recovered, all nervousness and urethral irritation disappearing. Here, then, was a perineal abscess, the result of traumatism, opening both into the urethra and rectum, the urethral orifice closing. Microscopy revealed no gonococci. The following case is rare, only a few of the kind having been reported. Wyeth reports one, to whom I am indebted for the technique of the operation. This case was the result of lithotomy.

J. W., aged 55, occupation, cashier. When 9 years old lithotomy was performed by a prominent Pittsburg surgeon and relieved successfully of a large calculus. His recovery was uneventful, but soon after patient noticed unnatural sensations which convinced him of a connection between his rectum and urethra. Urine passed in large amounts per rectum. Gas and fecal matter per urethra. He consulted various physicians who assured him that such was not probably the case, nor consistent with his apparent good health, and after several years of futile medication he suspended treatment. In October, 1895, after a lapse of twenty years, his condition growing worse, he consulted his physician, Dr. E. L. Neff, of Allegheny, who found a communication between the urethra and rectum by injecting into the urethra several ounces of a weak solution of permanganate of potash. The fluid was found in the rectum. Dr. Neff kindly referred the case to me, when another examination was made. The finger revealed a normal rectum except above the sphincter anteriorly where it passed into a deep sulcus. Passing a sound through the urethra and inserting a speculum into the rectum, a probe readily demonstrated a recto-urethral fistula, the urethral opening being in the membranous portion. The fistula was fully one-half inch in diameter throughout, since the finger passed through readily. A solution of hydrogen peroxid was then thrown into the urethra and readily appeared in the rectum. The wall of the fistula was dark and callous and the rectal orifice more or less irregular. There was no doubt in the diagnosis of a large patulous tract between these cavities. Nov. 2, 1895, Drs. Neff and Adair assisting, an attempt was made to close the fistula. Two crescentic flaps were made about the fistular orifice, the primary incision about a half inch from the margin going through the muscular coats of the bowel. The flaps were dissected up to within an eighth of an inch of the margin between which and the opening the flaps were to receive their nutrition; they were turned toward each other, the rectal mucous membrane becoming the urethral floor, the raw surface being in the bowel. A line of catgut sutures was placed about a fifth of an inch apart, a rubber tube was placed in rectum for the escape of gas, and a silver catheter retained for ten days through which the bladder was flooded with Thiersch's solution each time after the patient voided urine. The wound healed kindly and promptly, and a complete obliteration of the fistula was assured, but a few months afterward patient still complained of small quantities of urine in rectum and gas in urethra, which was only occasional, however. Since the operation, no fecal matter has appeared through the urethra and other abnormal phenomena very much modified. An examination showed a minute orifice at the upper angle of the wound which failed to unite. The patient is anxious to have this closed which he will allow us to do the coming autumn, when we hope to fully succeed. There was no extravasation of urine and his general health is much improved. The importance of the rectal tube can not be overlooked in promoting the healing process with a view of obliterating fistula between rectum and urethra, or vagina. The neglect of this precaution has caused many failures in closing recto-vaginal fistula on account of gas infecting the wound.

(To be continued.)

American Pediatric Society.

*Eighth Annual Meeting held at Montreal, Canada,
May 25, 26 and 27, 1896.*

Owing to the necessary absence of the President, DR. JOSEPH O'DWYER, the first Vice-President, DR. JAMES C. WILSON, presided. The first session was opened by the reading of the President's address, entitled

THE EVOLUTION OF INTUBATION.

This was prepared at the request of the Council and was a paper of interest as it described the labors which Dr. O'Dwyer pursued with untiring devotion to a great idea through five long years. A bivalve tube was first used but after three years of continuous effort it was abandoned and experiments were begun with the solid tube. The paper described the various experiments made with alternating failure and success, until at last obstacle after obstacle had been overcome, and imperfection after imperfection had been removed. As a result of this patient toil, perfected instruments were given to the profession, a very rare thing in the history of medicine. The various steps taken in the attaining of this result were narrated with the simplicity and modesty which has always characterized the literary work of Dr. O'Dwyer.

The first paper was read by Dr. GEORGE N. ACKER, of Washington, on "Gangrene of the Lung following Typhoid Fever." Dr. J. H. FRUITNIGHT, of New York, read a paper on "Malignant Endocarditis" and presented a specimen. As the bacteriologic examination showed the condition to be due to the presence of streptococci, the author advocated the use of streptococcus antitoxin serum in such cases.

At the second session, Dr. A. H. WENTWORTH, of Boston, read an exhaustive paper on "Lumbar Puncture" and reported twenty-nine cases. He affirmed that while normal cerebrospinal fluids contain neither fibrin nor cells and is always clear, it is always cloudy in cases of meningitis, though the cloudiness is sometimes very slight. This is caused by cells, the character of the cells differing with the variety of meningitis. The operation, the author believes, offers a valuable means of diagnosis. For such purpose, however, the microscope is essential and inoculation experiments are also of value. This was followed by a paper on "Tapping the Vertebral Canal," with remarks on local treatment for tubercular meningitis, by Dr. AUGUSTUS CAILLÉ, of New York. He reported twenty-one cases, and believed that a study of the cases reported up to the present time will certainly convince the most skeptical that Quincke's puncture is of positive value as a method of diagnosis. It is simple and usually easy of performance. In two cases Dr. Caillé injected antiseptics into the sub-arachnoid space but without material results. He proposes in some future case to lay bare the dura by removing a button of bone and irrigating from a lumbar puncture upward through an opening in the dura.

Dr. C. G. JENNINGS, of Detroit, also read a valuable paper "Lumbar Puncture," and reported practical experience.

Dr. FLOYD M. CRANDALL, of New York, read a paper on the "Occurrence of Influenza in Children" and reported local epidemics.

Dr. SAMUEL S. ADAMS, of Washington, reported an extremely interesting case of "Temporary Insanity following Typhoid Fever."

Dr. FREDERICK A. PACKARD, of Philadelphia, reported a case of "Endothelioma of the Brain with Atrophy of the Paralyzed Members."

Dr. HENRY JACKSON, of Boston, read a paper on "Nasal Feeding in Diphtheria," in which he advocated feeding by means of a soft tube passed through the nose into the esophagus in certain cases of diphtheria. As this can be done with ease, it does much in preventing exhaustion of the child's strength.

Dr. WILLIAM OSLER, of Baltimore, read a paper on the

CLASSIFICATION OF TICS OR HABIT MOVEMENTS.

He made the following classification: 1. Simple tic or habit spasm. 2. Tics with superadded psychic phenomena: *maladie de la tic convulsif*; or Gilles de la Tourette's disease. 3. Complex coördinate tics. 4. Tic psychique. An imperative idea is the psychic equivalent of, and has an origin similar to, the motor tic. Each of these subdivisions was elaborated, and illustrated by practical examples.

The third session was devoted to the antitoxin treatment of diphtheria. The report of the Collective Investigation Committee of the Society upon the results of the antitoxin treatment in private practice was read. Over five thousand cases were reported, the results being, on the whole, far more favorable than any extended reports have thus far appeared. A complete report will soon be published in full.

Dr. A. F. PACKARD reported favorable results of the antitoxin treatment and Dr. S. S. ADAMS read a paper on the "Comparative Results of the Treatment of Diphtheria with and without Antitoxin in the District of Columbia." It appears that the death rate from diphtheria in the District of Columbia since the introduction of antitoxin has materially diminished.

Dr. A. SIEBERT of New York, read a paper on

SUDDEN DEATH AFTER ANTITOXIN INJECTIONS.

He reported a series of striking experiments which showed that the injection into animals of carbolic acid even in very weak solution was constantly followed by most characteristic spasmodic movements. Another series of experiments was made to determine the effects of subcutaneous injections of air. The results seem to show that antitoxin can contain but infinitesimal quantities of carbolic acid. They also render the proposition reasonable that the few sudden deaths reported after the injection of antitoxin might be due to the injection at the same time of air.

The general discussion elicited by these papers was extremely interesting and showed unanimous and very strong sentiment in favor of antitoxin.

At the fourth session, Dr. ROWLAND G. FREEMAN, of New York, read a paper on "Low Temperature Pasteurization of Milk at about 67 degrees C." He proved that this temperature was sufficient to kill numerous pathogenic bacteria and various atmospheric bacteria, and referred to the importance of avoiding unnecessary heat in the preparation of milk for infant's use. He presented a new apparatus of simple construction, designed to pasteurize milk at 67 C. Dr. CHARLES W. TOWNSEND, of Boston, reported several cases of "Thigh-Friction in Infants." Dr. WILLIAM P. NORTHRUP, of New York, reported a most interesting case of "Apparently Relapsing Cerebro-spinal Meningitis" followed by death and autopsy, which elicited a warm discussion on the pathology and diagnosis of meningitis. Dr. HENRY LAFLEUR, of Montreal, reported a case of "Insolation in an Infant of Thirteen Months." Dr. A. D. BLACKADER, of Montreal, reported a case of "Enlargement of the Liver" in a young child with symptoms closely resembling those of typhoid fever.

Papers were read by title by Drs. B. K. RATCHFORD, of Cincinnati; F. FORCHHEIMER, of Cincinnati; IRVING M. SNOW, of Buffalo, and HENRY D. CHAPIN, of New York.

The last session was devoted to the presentation of pathologic specimens, specimens being presented by Drs. Rotch, Holt, Caillé, Adams, Packard, Acker, Freeman, and Townsend.

In the executive meeting, the following officers were elected for the coming year:

President, Dr. Samuel S. Adams, Washington, D. C.; first vice-president, Dr. W. S. Christopher, Chicago; second vice-president, Dr. Charles W. Putnam, Boston; secretary, Dr. Frederick A. Packard, Philadelphia; treasurer, Dr. Charles W. Townsend, Boston; recorder and editor, Dr. Floyd M. Crandall, New York; member of council, Dr. William Osler, Baltimore; chairman of council, Dr. William P. Northrup, New York.

The Ohio State Medical Society.

Annual Meeting held at Columbus, May 27-29, 1896.

The Society was called to order in the Hall of the House of Representatives, Columbus, May 27, the President, Dr. MILLIKIN, in the chair. An address of welcome was delivered by Mr. GILBARGER, and responded to by the President of the Society.

Dr. JAMES E. PILCHER, Captain Medical Department U. S. A., Columbus, read a paper on

THE PRESENT STATUS OF MILITARY MEDICINE AND SURGERY AND ITS RELATION TO GENERAL PRACTICE.

Military medicine and surgery are simply medicine and surgery adapted to the needs of military work. The relative importance of medicine and surgery in military work may be deducted from the fact that less than one-third of the fatalities in the late war were due to surgical causes. The first duty of one in the medical department of the army is to investigate the sanitary conditions and report fully. In military work the lightning operators are more necessary than in civil surgery. The engagements of the future will probably be more rapid than in the past and it will be impossible to remove the wounded from the field before treatment. The troops, therefore, must be instructed in the art of self-aid. The removal of the wounded from the field will probably hereafter be done after the engagement. This is done by the hospital corps, a band of men under the direction of the Medical Department. These men have charge of the nursing in the hospitals.

Dr. WILLIAM THOMAS CORLETT, Cleveland—"Modern Status of Specific Urethritis, with its Treatment." The essayist took up specific urethritis in the male, its course, complications and treatment. The best results were obtained from the use of permanganate of potassium, gr. ss i to ten ounces of water. Irrigation had also been used with advantage. The water should be 100 degrees F. The disease is self-limited, and we

know no means by which the gonococcus may be quickly destroyed without irreparable damage to the urethra. A free discharge of pus favors the elimination of the poison. Later in the disease topical applications hasten recovery, which may be regarded as complete when upon repeated examination the organism can not be found.

DR. F. F. LAWRENCE, Columbus—"Salpingitis." Salpingitis is always a secondary disease. Gonorrhea plays a role in etiology which has been generally overestimated. Other causes are abortion, the use of unclean instruments, etc. Some cases are largely due to a peculiar condition of the patient, in which there is a tendency to suppuration on the slightest injury or inflammation. Inflammation of the tube can rarely if ever be separated from ovaritis. Salpingitis should never be operated upon, except symptoms of infection are manifest. It is curable without operation and should be so treated. Acute septic salpingitis is always dangerous and often rapidly fatal, and should be operated upon if the patient has a chance of recovery. Chronic suppurative salpingitis should always be removed. Tubercular salpingitis, if no other structures are involved, should be removed. The essayist condemned the attempt to do too much, for instance, the removal of the uterus when the tubes or ovaries only are affected.

DR. GEORGE W. CRILE, Cleveland—"Research into the Technique of Laryngeal Operations, with Report of Four Successful Total Extirpations." The technique was based upon operations upon dogs and the cadaver. The cases reported comprised three of carcinoma and one of tuberculosis. The Doctor advised the introduction of the tracheal tube before operation, and after operation the food should be taken through the tube. In five neurotics there was no nausea from the tracheal tube. The radical operation is sometimes indicated for relief even when cure is impossible. When early recognized, the result of operation will probably be favorable, because the disease does not readily extend through the cartilage. Atropia hypodermatically guards the heart but not the respiration. Cocain, on the other hand, locally applied, guards both the heart and respiration absolutely, even though general anesthetics are employed.

SECOND DAY—MORNING SESSION.

DR. L. B. TUCKERMAN, Cleveland—"Is It Grip, or What?" The Doctor had recently met an unusual number of cases of weak heart with no appreciable lesion of either the heart or lungs. The depression was marked and the treatment used was aperient and tonic. The phenomena seemed to be of nervous origin, and the essayist suggested the name *bradycardia febrilis*, if the condition is not grip or an obscure case of malaria.

DR. S. S. HALDERMAN, Portsmouth—"Antitoxin in the Treatment of Diphtheria with Report of Fatal Termination of Case after Receiving Prophylactic Dose." (Published in the JOURNAL of June 13, p. 1168.)

DR. J. E. FACKLER, Versailles—"The Treatment of Diphtheria."

Early in the Doctor's experience he was impressed with the favorable results obtained from the use of chlorin in the treatment of certain zymotic diseases, notably, typhoid fever. Reasoning from analogy, the use of it was extended to the treatment of diphtheria, and for more than a quarter of a century the chlorin treatment has proven uniformly successful in the practice of the author and of neighboring physicians who have made use of the remedy. Not a case under this treatment has proven fatal thus far.

DR. R. E. SKEEL, Cleveland—"The Etiology and Prophylaxis of Puerperal Sepsis."

Puerperal sepsis is largely due to the action of infectious material to be found normally in the body. Thus, the vagina normally contains microorganisms, inhibited in action during health by the normal secretions. Any dead material as following abortion, should be promptly removed. For the same reason puerpera should sit in the erect position during micturition and defecation, if possible. Antisepsis and asepsis should be observed, beginning with the bath and clean clothing.

DR. M. STAMM, Fremont—"Intestinal Obstruction, Some Diagnostic Points and Treatment."

Pain is not intense and continual in the initial stage. Collapse is generally absent or much less frequent than in strangulation. The inflated coils and their peristaltic movement can be readily detected at the seat of obstruction in the distended abdomen. Some trouble in connection with the bowels has generally preceded the onset of ileus. The Doctor then presented the list of questions furnished by Obalinski. Treatment: With rest, diet and small doses of opium a great many cases of circumscribed peritonitis do well, and even some cases of diffuse peritonitis will recover. If the presence of pus can

be detected an incision should be made in that region and not in the median line. In cases of obstinate vomiting, lavage of the stomach promises great relief. Where the heart begins to fail and to cover the great loss of fluids from the tissues, infusion of salt water often proves of great benefit. Meteorism may call for puncture with the aspirator or hypodermic needle. If with the general signs of obstruction we find a large distended coil, with local meteorism and increased peristalsis, little doubt can exist it is a case of strangulation or volvulus, and we should resort to laparotomy at once. If a foreign body causes obstruction, its extraction by incision would be the proper procedure. In cases of stricture, anastomosis or resection is indicated. If due to compression by a tumor, enterotomy or resection are the preferable methods. In cases where there is some doubt about the nature and seat of obstruction, enterotomy or a fecal fistula would present the best temporary hope. In intussusception or invagination, we may at first try injection of large quantities of water in the genu-pectoral position, or insufflation of air into the rectum. If the invagination is low down, massage, sponges attached to a probe or stem, or the finger alone, may be employed for its reduction. Should all of this prove of no avail, disinvagination by laparotomy will have to be attempted, and where this method fails or where gangrene is already present resection would be the only expedient.

The President, DR. DAN MILLIKIN, then read the annual address

A STUDY IN CREDULITY.

The essayist traced the course of credulity in man from the first or primeval state, when man was simple in his tastes like the child and the savage, to the advanced stages of civilization of to-day, showing wherein the people of the present are possessed with unscientific ideas, superstitions, regarding the nature and cure of disease. The President declared that superstition found its food in disease, and that it was easy enough for the savage to clothe disease in some poetic or simple idea, making disease some terrible monster or demon. But even in the higher civilization of the no distant past, and even in the present, people regard disease as some terrible "it" traveling from one part of the body to another, which can only be cured by some imaginary charm or superstitious custom. The Doctors are not proof against the great wave of superstition or credulity that possesses the people, for it was only a few years ago that bleeding was regarded as the means by which disease could be let out of the body, or that intolerable drugs were poured down throats until either the disease had to go or the soul of the patient. The physician is not alone responsible for these superstitious ideas prevailing but the surgeon also clings to some of the old ideas and practices in his profession and can give no excuse for their existence: as for instance, his use of chloroform. The old credulity breaks out anew at every new discovery in bacteriology. The essayist then paid his respects to the patent medicines, condemning without stint many proprietary compounds. The remedy for all this credulity or safe-guard against more of it, is that the doctors should become scientific, should investigate for themselves, should become closer students of materia medica. The medical profession is not a credulous profession as a whole, and the doctors of the present and future should work out the principles of their science as the scientists in other branches work out the laws and hypotheses.

DR. B. D. MILLIKIN, Cleveland:

SOME OF THE ACCIDENTS OF CATARACT OPERATION.

Of the class of accidents occurring at the time of operation, we have: First, the iris falling before or upon the knife blade; second, the incision into the cornea may be too small to admit the escape of the lens; third, the escape of the vitreous; fourth, luxation of the lens; fifth, hemorrhage; sixth, prolapse of the iris, and seventh, infection. Those accidents occurring after an operation has been completed, may be enumerated as follows: First, prolapse of the iris; second, hemorrhage; third, accidents of more or less gravity resulting from the restlessness of the patient or striking against foreign substances, such as the hands, bed posts, etc.; fourth, infection.

DR. M. ROSENWASSER, Cleveland:

A PLEA AGAINST THE MEDDLESOME TREATMENT OF ACUTE GONORRHEA IN WOMEN.

The title explains quite well the nature of the paper. The author condemned the "early and thorough" treatment as meddlesome and mischievous for the following reasons: It is based on a pathology now discarded as crude and imperfect; it is not applicable to all the tissues simultaneously affected, and hence, it is no cure; the results at the end of the acute stage, are no better than those of a more rational though less

exacting treatment: it is cruelly painful and often dangerous, requiring an anesthetic for its proper execution; it is impracticable, even in the hands of an expert: though the treatment is irrational, inefficient, severe and dangerous: the physician who does not practice it is stigmatized as old fashioned, negligent, and indifferent to the interests of his patient.

Kentucky State Medical Society.

Forty-first Annual Meeting, held at Lebanon, June 10-12, 1896.

FIRST DAY—MORNING SESSION.

The meeting was called to order by the President, DR. JOHN A. LEWIS, of Georgetown, at 11 A.M.

The opening prayer was made by Rev. Dr. Bracken, of Lebanon.

The address of welcome was delivered by B. J. LANCASTER, of Lebanon. He referred feelingly to the fact that forty years ago the Kentucky State Medical Society met in that city, and reminded the members that his instructions were to extend the welcome on behalf of the citizens even more heartily than so many years ago, if such were possible. He referred also to the fact that Dr. W. W. Cleaver, a citizen of Lebanon, now present, was perhaps the only one who was present forty years ago.

The Chairman of the Committee of Arrangements, DR. R. C. MCCORD, welcomed the members on behalf of the Marion County Medical Society.

DR. STEELE BAILEY, the Permanent Secretary, referred to the sound condition of the Society, and said that at the present time there were more county medical Societies throughout the State than ever before and this was attributed to the efforts of the State Society. He referred to the fact that there had been three deaths and four resignations during the year.

On motion of Dr. McCormack, who presented a resolution from the State Board of Health, the President will appoint a committee of five to urge upon the Legislature at its next meeting a statute to punish the crime of abortion.

A symposium of papers upon Bright's disease was begun by a paper from DR. E. S. SMITH, of Hodgenville, upon

PARENCHYMATOUS NEPHRITIS.

A review of the early pathology was made leading up to the present pathologic classification, which is not satisfactory to all. Credit was given Rokitsky for having first classified it as a part of a general condition. The large, smooth, white kidney received the most attention as the typical form of this variety. The symptoms are typical of this form, though they all have a line of symptoms common to all. In the parenchymatous form there is a history of an acute attack; dropsy more common than in chronic form, not confined to any particular tissue but changes capriciously from one locality to another part of the body. Changes in blood common and prominent: face is pale, cutaneous surface white, smooth and glossy; blood more watery, poorer in albumin and red corpuscles: urea, uric acid and white corpuscles relatively increased. Uremic phenomena common, headache, defects of sight and hearing, convulsions and coma. The most logical question is the great absence of convulsions in Bright's disease; 90 per cent. are not so affected; convulsions constitute the exception. The various symptoms met in so-called uremic poisoning is difficult to explain upon hypothesis of poison in blood. Excitant, convulsant or narcotic symptoms rapidly follow each other in same case. That these nervous symptoms are caused by cerebral transudation seems most rational, this causes compression of smaller blood vessels and intense uremia of structures. If effusion in subarachnoid space or over cerebrum, coma ensues; if at base of brain, convulsions. Another significant fact is, the treatment which is most effective is that which relieves edematous effusions. The consideration of treatment is under three heads: 1, prevention of further extension of disease; 2, the relief, if possible, of organic changes; 3, the relief of troublesome symptoms. Under first, ascertain and remove cause if possible; diet, rest and clothing regulated: milk diet important. The second indication has not given so satisfactory results. Some think highly of bichlorid of mercury in doses from 1-36 to $\frac{1}{16}$ grain. Troublesome symptoms, as diarrhea, relieved by dieting, ice by mouth, bismuth, oxalate of cerium and opium; anemia by iron alone or with cod-liver oil: dropsical effusion by digitalis, caffeine, scoparius, hydragogues, as calomel and jalap. Patient may be carried off by uncontrollable diarrhea. Venesection must not be forgotten. Diaphoretics have their place.

DR. GEO. E. DAVIS, of Salvisa, read a paper on

CHRONIC INTERSTITIAL NEPHRITIS.

Probably the most fertile source of unsuccessful treatment

is erroneous diagnosis. Upon an accurate and timely diagnosis depends the correct management of the case. The symptoms taken singly may not be characteristic, but when taken collectively are of diagnostic importance and pathognomonic import. Symptoms are sonorous noises in ears, vertigo, asphyxia of extremities, itching, nocturnal cramps in legs, increased arterial tension, gradual loss of flesh in some cases, incapacity for mental and physical exertion, insomnia, headache, urine may reveal no abnormality, decreased toxicity and reduced specific gravity. Presence of casts while not general is ominous. First symptoms may be of alimentary tract, dyspnea, harassing cough, palpitation of heart, increased arterial tension, edema, disorders of vision, night sweats, increasing anemia, frequent urination. The microscope is much more generally employed and recognized of more importance as a diagnostic means and rightly so. Albumin is increased by full meal and exercise. The reduced toxicity of the urine, or a diminution of its solid elements, is of greater significance of early renal changes than albumin and casts. An interesting case was reported showing an association of symptoms as stated above. In treatment not much progress has been made. Mercury and iodids exercise favorable influences. Digitalis has no essential effect over kidney structures itself, relieving renal insufficiency by increasing arterial tension and stimulating and toning heart. Best results are secured by giving large doses at long intervals at bedtime; strophanthus must be repeated at short intervals. Water is a safe promoter of renal secretion and is best diuretic. Natural alkaline mineral waters have good effect on digestive disturbance. Tatham water exerts a beneficial influence in many cases. Stimulate function of skin and bowels to aid elimination. Diet is important; milk diet lowers specific gravity but increases albumin excreted. Anemia combated by combination of gold and arsenic; bromid of soda for insomnia.

DR. R. C. MCCORD of Lebanon read a paper on

AMYLOID KIDNEY.

In this form we have to deal with a degeneration which is always chronic without any acute stage or in any sense local. Its origin is in changes which pervade the whole frame and produce tangible alteration wherever arteries penetrate. It may invade other organs simultaneously. No alteration in size of kidney or their appearance when arteries principally involved; ocular inspection tells little, but iodine test is great aid. The amyloid tissue is colored a deep reddish brown. Late, the kidneys are increased in size. Microscopic examination shows alteration in walls of blood vessels, Malpighian tufts, vasa recta. It never occurs in those in perfect health, and occurs in connection with chronic suppuration and syphilis. Early symptoms are indefinite, but late easily recognized. The train of symptoms follow prolonged suppuration or syphilis. He loses flesh and strength. Dyspeptic symptoms and shortness of breath develop. Urine is increased in quantity, pale, low specific gravity; casts not abundant. Pale waxy complexion. Differential diagnosis not difficult. Prognosis is uncertain. If due to suppurative causes deposits will continue to increase as long as drain continues and no longer. If cause not removable, death follows. Give antisyphilitic treatment, when syphilis is present. If albumin is present and surgical operation indicated, the albuminuria increases the danger from the operation *per se*, and there is additional danger from the anesthetic. The dangers are usually from exposure and prolonged narcosis.

DR. CARL WEIDNER of Louisville, read a paper on

DIAGNOSIS OF THE DIFFERENT FORMS OF BRIGHT'S DISEASE.

Classification recognized as acute and chronic form. In acute form a nephritis is referred to in which uriniferous tubules with their lining membrane is chiefly involved, and form in which interstitial connective tissue is principal seat, but may have combination of two forms, if localized, a glomerular nephritis. Amyloid or waxy kidney occurs independently of previous kidney disease and simultaneously with the same changes in other tissues or organs. Examination of urine is very important and mostly aids in diagnosing different forms. Changes in urine have characteristics more or less common to all forms, in quantity, general physical character and chemie composition, and presence of certain organized morphologic elements. Acute nephritis, chiefly of diffuse form, quantity is diminished, to few ounces or pint in twenty-four hours, or suppression. With improvement urine increases in quantity, or increased when rapid absorption of dropsical effusion takes place. Specific gravity low in relation to quantity, cloudy, high color, albumin in large amount, urea, uric acid and chlorids diminished. Microscopic examination shows leucocytes, red blood cells either well preserved, discolored or swollen; blood casts, hyaline casts in various stages of degeneration, and renal epithelia. In chronic interstitial nephritis the quantity is increased, resembling diabetes insipidus; low specific gravity;

pale and greenish in color, frequency of urination increased, urine clear, no sediment; acid reaction; urea lessened, albumin in small quantity or absent temporarily; fat seldom present; blood thin, leucocytes and renal epithelium small in number; tube casts few, mostly hyalin and granular. Chronic parenchymatous nephritis the quantity varies. Specific gravity lowered in proportion to quantity, 1010 to 1018; light yellow color, frequent urination; acid reaction; urea lessened; albumin always present in considerable amount; fat present in late stages; blood also; leucocytes in large numbers; tube casts always present in large number of all varieties. In amyloid kidney urine resembles that in interstitial form, increased quantity, light color, clear, small albumin, 1010 to 1018 specific gravity; very long hyalin casts extending frequently through several fields, late they are very long and wide.

DR. HENRY E. TULEY of Louisville read a paper on

NEPHRITIS IN CHILDREN.

Nephritis in childhood may be primary or secondary, the latter due to exanthemata, rheumatism, erysipelas, acute and chronic intestinal diseases, vaccination and pneumonia, the active causative agents being primarily of bacterial origin or result of elimination of toxins. Lesions may be descending nephritis, the essential change being glomerular and epithelial, or ascending due to invasion from urinary organs below. Councilman describes changes as simple degeneration of glomerular epithelium with or without exfoliation, or it may be a glomerulo-capsular nephritis, lesion may be of croupous pneumonia type. Emphasis was made upon importance of frequent examination of urine of infants too often neglected. Catheterization resorted to if necessary. Cold and exposure, long bathing in sea water or fresh, may be cause of primary. Symptoms may be misleading, may be trivial, the younger the patient the more the symptoms may point to brain, lungs, or gastro-intestinal tract. Onset sudden, temperature high; pulse rapid, high tension; early edema; blindness, retinitis; scanty urine, high colored; albumin, microscopic examination showing renal derivatives; anemia; cough; waxy, dry skin; pain in back, headache, restlessness, insomnia, strabismus. Relieve kidneys of extra work of carrying transuded serum; restore kidney to normal condition, endeavor to prevent further damage to diseased organ. Calomel and salines; hot-air bath; acetate of ammonia; venesection; pilocarpin, which is very uncertain in its action; water ad libitum by mouth and large enemata. Diuretin is recommended by some.

DISCUSSION ON BRIGHT'S DISEASE.

DR. JNO. G. CECIL, Louisville—The five papers have covered the ground most elaborately and completely. The pathologist is disposed to subdivide too much. The simple division of acute and chronic parenchymatous and chronic interstitial is all that is necessary for the clinician. The parenchymatous forms are clear in outline, but it is the interstitial form which is of the greatest importance. All life insurance companies magnify the importance of chronic interstitial nephritis, placing it hardly secondary to tuberculosis of the lung. It is insidious and affects the most important citizens of a community, following a life of dissipation it is true, but it is too often found in others who dissipate in work, especially brain work, and unfortunately we find it out too late. This variety creeps on us before we are aware of it. We all know the close relationship between the arterial system and the form of nephritis. All authorities are agreed that arterio-sclerosis is almost invariably associated with it and the great question is: Which goes first, the nephritis or the arterial change? In many instances arterio-sclerosis precedes chronic interstitial nephritis and if we can demonstrate the fact that a man has arterio-sclerosis, we can warn this man of impending trouble. "A man is as old as his arteries." A train of symptoms as headache, nausea, vomiting and diarrhea leads to an ophthalmoscopic examination and the diagnosis can be made early. It is an obscure disease and we can not depend on the symptoms. Anything which will suggest chronic interstitial nephritis should be seriously considered.

DR. WM. CHEATHAM, of Louisville—The ophthalmoscope in many instances has revealed a nephritis never before suspected. In large majority of cases of neuro-retinitis albuminurica seen by the speaker in the last twenty-three years, nephritis was not suspected. Usually glasses are recommended on account of failing vision, though the latter may not be present. Typical cases of papillo-retinitis nephritica may be found with perfect vision. The ophthalmoscope is important in diagnosis and prognosis. It indicates advance or recession of the trouble; a large majority of nephritis in which retina and optic papilla are involved do not live for more than six months or one year. Anatomic lesions in arteries, veins and capillaries are hyalin

thickening and sclerosis, thrombosis and occlusion, said to be due to transuding white blood corpuscles, which degenerate; numerous dilations of capillaries with small aneurysms, liable to occur in all parts of the circulation of the eye, but more often in the retina; hyperplasia of connective tissue often found; if blood vessels extend into inter-granular layers we have hemorrhages; edema of retina with cavities filled with coagulated fluid; granular and fatty degeneration of Muller's supporting fibers; white patches of fatty degeneration; rods and cones may remain normal or become edematous; pigment may remain normal, be absorbed or become swollen; amyloid granules are found in the chiasm and optic tract. Sclerosis of the vessels causes all these changes, more often in retina because its arteries are end arteries with little or no collateral supply. Length of life from a few weeks or a few months, to seventeen years; average of life after involvement of retina, one year. Uremic amblyopia in chronic nephritis usually sudden and permanent. There is occasionally recovery with blindness.

DR. CHAS. W. AITKEN, Flemmingsburg—Dr. Cecil referred to the insidious onset of the interstitial form and that we are likely to overlook it, and not likely to confound it with other kidney lesions. Dropsy is more marked in parenchymatous form than the others. The limbs are swollen at night, the face in the morning, and inflammation of serous membrane and uremia is more likely to occur than in others. Dyspepsia is common, skin dry and harsh, neuro-retinitis should suggest careful urinalysis. Scant high-colored urine, high specific gravity, albumin, fatty and hyalin casts. Dilatation and probably valvular lesion of heart is so common that it is generally mentioned in conjunction with nephritis on the death return. In treatment support strength, guard against exacerbations and meet various symptoms. Strychnia for the heart, nitro-glycerin for the headache, pilocarpin with morphin for uremic intoxication and the latter for dyspnea.

Interstitial form is insidious; dyspepsia; frequent desire to urinate. Close observation may detect dropsy. Sixty ounces of urine may be passed in twenty-four hours; low specific gravity. Hypertrophy of left ventricle: accentuated second sound over aortic interspace; headache, insomnia, irritable temper, capricious appetite, peculiar breathing and death by coma, convulsions or intercurrent affections. The treatment is nutritious diet, warm milk; warm dry climate; no intemperance; potassium iodid, mercury and iron. In amyloid kidney there is increased flow of urine, previous existing disease as a rule, low specific gravity, little or no albumin, waxy cachexia. Palliative treatment unless one can remove the cause. These are "every day" diseases and must be looked at on the practical side.

DR. J. B. MARVIN, Louisville—I am satisfied that time would be saved if the term Bright's disease was narrowed down to those forms of nephritis described by Bright. The amyloid kidney is not a nephritis or a Bright's disease, but is purely a secondary condition following syphilis, tuberculosis of bones and lungs; and the treatment consists in the prevention. The interstitial nephritis was not considered by Bright. It is the most treacherous and the least amenable to treatment. The acute parenchymatous nephritis tends naturally to rapid recovery or death; the tendency with careful nursing is toward recovery. In chronic parenchymatous nephritis the association of anemia and dropsy makes it difficult to overlook. A point in the treatment which was not emphasized enough, is rest; rest in bed. Nothing reduces the amount of albumin quicker. The climatic treatment is good, these patients should leave our climate here with its sudden changes and go to Southern Georgia or Texas, where it is not too high, but where the temperature is equable and dry. Wool should be worn next the skin continuously. One of the essayists condemns pilocarpin. Do not give it by the mouth, but hypodermatically. The symptoms of depression are always combatted by atropia. As to the cause of convulsions by potash salts retained in the blood, why not substitute the soda salts? Don't use digitalis as a diuretic; it is not nearly so good as generally thought. In regard to the interstitial variety and the low tension pulse spoken of by one of the essayists, I disagree with the essayist on this point and regard this as a dangerous symptom. Cases are seen with a hard, high tension pulse years before interstitial nephritis is recognized, and it would be better if we possessed more of the expertness of our forefathers in the feel of the pulse and we would more often be on the track of an interstitial nephritis. Urine, pale in color, of low specific gravity, hard pulse, hypertrophy of left ventricle with absence of valvular lesion, is a strong suspicion of interstitial nephritis. A high tension pulse, associated by bronchitis, asthma, is a suspicion developing in a middle-aged man. Diet, climate and clothing are the best remedies. Three beneficial agents in high tension pulse, are potassium iodid in moderate dose, diluted;

chloral hydrate, not by mouth but by rectum in milk: it reduces temperature also: nitro-glycerin and nitrate of amyl; the former is best, after the first dose tolerance being readily attained. Morphia may kill. There are two separate forms of uremia: Coma and convulsions, the latter with high tension pulse; but with low tension pulse the tendency is to coma and here use morphia sparingly.

DR. W. C. DUGAN, Louisville—It is important to examine urine in surgical cases. I have seen several cases in which death resulted from neglect of this. If an operation must be done to save life, as appendicitis with abscess, you must tell the friends that there may be suppression. Local anesthesia should be used more frequently. I rise simply to urge examination of urine in all cases.

AP MORGAN VANCE, Louisville Surgeons generally understand that amyloid kidney can be cured if the suppurating organ or bone is operated upon. I would like to ask if this operation is done thoroughly will the kidney degeneration disappear.

DR. LOUIS FRANK, Louisville—Frequent examinations of urine may not find albumin, and these cases go on and die after major operations, whether ether or chloroform has been given. In regard to the case reported by Dr. Tuley, it hardly seems possible that one ounce of blood drawn could have caused so remarkable a result; the improvement must have been due to some other cause.

DR. ARCH. DIXON, Henderson—Less than two months ago a surgeon in Henderson did a vaginal hysterectomy in a patient 45 years old. I asked the question if the urine had been examined before the operation. He said it had and the result was negative. The operation was done nicely but the patient died on the fourth day with suppression of urine. A microscopic examination should have been made of the urine also.

DR. R. C. McCHORD, Lebanon—Conservative surgery in amyloid kidney is not good surgery. The disease is stopped effectually if the cause is removed. If death follows operation, it is in most cases from exposure during the operation and the prolonged narcosis.

DR. CARL WEIDNER, Louisville—The patients with neuro-retinitis are not recent cases. It arises as a complication and the subjective symptoms, as dyspnea, dyspepsia, up at night to pass urine, edema. Casts and albumin may be present and no retinitis. The amyloid degeneration is not a Bright's disease. It is found in many conditions, in men as a rule. It is impossible to cure it in view of the pathologic condition. There can not possibly be a revival of the cellular function. But cases may improve; for instance, occurring in a long joint trouble, the amyloid change may be local and not extend. Cases of sudden death after operation are obscure. One examination of urine may not show albumin or casts. Sudden suppression of urine and symptoms of uremia may develop. This may be due to a septic condition causing Bright's disease. Local shock of mechanism of kidney may occur, arresting kidney secretion.

DR. W. L. RODMAN, of Louisville, read a paper upon

INJURIES TO THE BRAIN.

This form of injury is of interest on account of fatality, or conditions worse than death in those who recover. In injuries to the brain, rather than its disease, surgery promises most. Good judgment and prompt action are essential to success. The nature of the cranium prevents drainage by other than surgical interference. Concussion is most frequently encountered in surgical practice; the name, however, is unfortunate. There is usually a macroscopic lesion. Any violence which may cause unconsciousness should be looked on as a severe injury. Keep in bed in a dark room for a week. After shock, recumbent position, mild stimulation by opium, cold to head, calomel, bromids, light diet. Compression may be caused by hemorrhage, depressed bone, inflammatory products and tumors, hemorrhage extra- or sub-dural. One of the branches of the middle meningeal generally gives way; perhaps its anterior branch most frequently. It can generally be easily diagnosed. A large trephine should be used and opening enlarged by mallet and chisel or rongeur forceps. Sub-dural hemorrhage generally accompanies depressed fracture. When dura is opened it should be done by semicircular incision one-fourth inch from bone, so that it can be accurately sutured after hemorrhage has been controlled; unless this is done, fungus or hernia cerebri will likely ensue. Non-chromicized catgut should be the suture material used. If cerebral abscess is large there will be hemiplegia of opposite side. Fractures are dangerous in proportion to accompanying injury to brain and membranes. There is too much thought of fracture, too little of damage to the brain. Dangers are immediate and delayed. We may have

fractures of vault or base; the former usually amenable to treatment, while damages to base usually preclude surgery. In punctured fractures make immediate trephining, free removal of bone, opening of dura, complete disinfection and drainage. Delayed operation in compound fracture is thirty times as fatal as those done at times of accident. In simple depressed fractures with symptoms of compression, trephine immediately. Fractures of base may occur in three fossae. The chief features to be kept in view are drainage and disinfection. If drum membrane has not been ruptured these fractures are compound, communicating with the external air through the Eustachian tube in naso-pharynx.

DISCUSSION.

DR. ARCH. DIXON, Henderson—One of the most important measures is to prevent sepsis. A few years ago I lost a case of basic fracture, there having developed a suppurative middle ear and infection from that. If there is a discharge from the ear or nose these canals must be rendered aseptic. The brain and cavity must be rendered aseptic and is as important as the peritoneal cavity.

DR. W. C. DUGAN, Louisville—Concussion is a misnomer, and the literature of the brain is to be rewritten. Unconsciousness following a severe blow, injury to the brain itself is found in nine out of ten. In linear fracture the inner table, which is very friable, is more extensively injured than the outer table. I have seen a patient go for a week after a blow; later headache develops; then unconsciousness. And operation was done and patient died. Do these operations early; do not wait for misnamed compression and paralysis. Mortality 40 per cent. in late operations, 1 per cent. in early operations. Epileptic habit is bad name; it is due to interstitial changes in brain, hence no relief from the operation. The mallet and chisel are to be preferred to the trephine. Hold the chisel at angle of 10 or 15 degrees to prevent the concussion caused by direct blow. Simple fractures which are inaccessible should be trephined. More frequent operation in basal fractures if able to locate place of fracture.

DR. AP MORGAN VANCE, Louisville—I wish only to sound a warning against opium in head injuries; it may mask coming symptoms.

DR. R. C. McCHORD, Lebanon—There is uncertainty in determining whether fractures of the skull exist if soft parts are not cut; no one can say positively without cutting down and examining.

DR. W. L. RODMAN, Louisville—The mallet and chisel at times are to be preferred. In all cases of fracture I shave the entire scalp, no matter how beautiful the hair. In fracture of base I am in favor of complete drainage and disinfection, which can not be obtained without operation.

DR. DUDLEY S. REYNOLDS here followed with a paper upon "A Term of Clinical Service."

(To be continued.)

Diminution in the Natality of the French Nation.—Dr. D. G. Brinton contributes to *Science*, May 8, the following paragraph on the subject of the above caption:

"This subject occupied a prominent place in the discussion of the anthropologic section of the French Association for the Advancement of Science at its last meeting. More than elsewhere, it deserves attention from the scientists of that nation, for out of the 86 departments into which France is divided, in 51 the deaths exceed the births. The annual natality for the whole country is only 23.7 for each 1,000 inhabitants, and this number includes the stillborn! To remedy this progressive depopulation, its causes must be ascertained. Dr. E. Maurel brought forward an interesting theory. He pointed out that the birth rate is lowest in those departments where food is most abundant and cheapest. The relation between these two facts he held to be the prevalence of hereditary arthritic diathesis (uric acid diathesis), leading to diminution of reproductive vigor in both sexes, this diathesis arising from excessive alimentation. Another speaker, Dr. Pommerol, attributed the diminished natality to voluntary restriction, while others suggested the increase of religious celibacy, the laws relating to the division of property, the lateness of marriages, and the decreased reproductiveness of women."

THE

Journal of the American Medical Association

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
 Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
 No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the Association living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JUNE 20, 1896.

THE ABUSE OF THE BROMIDS.

At the recent meeting of the Association of American Physicians, one of the papers that attracted most attention was that of DR. S. WEIR MITCHELL on the untoward effects of bromids in certain cases. He showed that the popular usage of these drugs is liable to lead to abuse, and that cases are not infrequent in which serious or even fatal bromid intoxication has occurred. The almost universal use of the bromids makes these effects the more important, as they are sometimes unrecognized by the physician, and still more often by the laity, who have learned to indulge in self-medication with these supposedly innocuous agents. While these facts have not been generally unknown to the profession, it is well to have attention called to them by an authority whose name will insure to any of his utterances a respectful consideration.

One point especially noted by DR. MITCHELL was the danger in certain cases of epilepsy of exciting a maniacal irritability that might sometimes amount to dangerous homicidal insanity by the use of the bromids. This is a possibility that is perhaps better known from experience by asylum physicians than by those in general or special practice outside of these institutions, but it is a little surprising that DR. MITCHELL should have been, as he declares himself, utterly skeptical as to its occurrence as late as ten years ago. At that time it had been many years a

matter of medical record, and had been discussed at length at the meeting of the American Neurological Association in 1881, when it seemed to have been quite generally observed. With very large doses of the bromids irritability and maniacal conditions are easily produced in certain insane epileptics, and it is quite possible, as DR. J. S. JEWELL then suggested, that some epileptics find their way to asylums through this idiosyncrasy.

The liability to mania or to excessive irritability is not the only individual peculiarity as regards susceptibility to the bromids. Within a short time an inquest was held on a man who died suddenly in London who had been taking the bromids very freely for neuralgia without exhibiting the usual symptoms of bromism, and a verdict rendered of death from heart weakness due to the medication. Whether the diagnosis was correct or not in this instance, it is certainly within the bounds of possibility, judging from the general depressing action of the bromids, that there may be individuals with idiosyncrasies that make these effects excessive and dangerous. The rarity of such peculiarities makes them only the more perilous when they do occur.

The bromids in moderate doses judiciously used rarely produce any serious effects in the hands of experienced and careful practitioners, and even in cases of exceptionally pronounced anti-bromid idiosyncrasies they can generally be discontinued before actual harm has been accomplished. The same can not be said when they are given in large doses, and more than one dram per diem may be considered large in many cases of epilepsy or when self-administered by the laity. Undoubtedly damage has been done by the popular usage of such preparations as bromo-soda, bromo-seltzer, etc., as was suggested in the discussion of DR. MITCHELL's paper. That they are also employed too frequently and inconsiderately by the profession is also probably true, and therefore his communication is a timely one. It is one of the utilities of a great reputation that it can give weight to utterances of what ought to be generally recognized truths, but which are likely from that very fact to be too often practically ignored.

HARDLY THE CODE.

One of our exchanges appears especially acrimonious regarding the late meeting of the AMERICAN MEDICAL ASSOCIATION at Atlanta, to the extent even of regret for absences from that most enjoyable "barbecue" with its juicy accompaniments. But speaking in the plural even though our calcitrant brethern were present we opine their enjoyments would not have been cut short by the brutal code, which "has brought death into our world and all our woe." There seems to have been a mock levity about the whole affair; sensoriums were in part not in a proper condition, for

which we are truly thankful, as a cause for the lack of bigotry which was in evidence since "old-coders and no-coders and new-coders, mingled freely together." Indeed, there was no action on the code question, which is very significant.

Again we join hands with our critics in the onslaught upon the supposed originals of likenesses in the lay papers, which seem to have been cartoons, without "criminal ears." For the last mitigation we are truly thankful. From a business standpoint we think that advertising should be restricted to certain classes; it would then be much cheaper and there would be fewer disappointments and a clear saving of at least seventy per cent. of our professional earnings. Still there is a hankering after ante-mortem fame which is rather hard to curb, else why should we run the risk of bulletins regarding the health of distinguished patients, the technical details of reporters and the steps of grand operations.

We think that the general profession has always been content with modest earnings and commendable acts of charity—that it gets but scant thanks for its good will toward men and more especially for its fealty toward the code, which thus far has condoned the faults of even vain-glorious leaders. At all events as some complaints have been made that the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION has "a monopoly of the papers and the discussions," we can but reply "why not, if it is to publish the entire proceedings?" The ASSOCIATION pays its own reporters it is true, but the doors are open. The ASSOCIATION owns its JOURNAL and it means to make it a successful one. Trade journals and medical publishers' journals have no claims superior to those of the ASSOCIATION itself, but they may send reporters if they wish.

Now to our critics we can only say that as regards the Code it is not we who are continually opening the gates of glory, or on the contrary that we are striving after the notoriety of detectives. Fortunately many of the evils of which we have spoken redress themselves and the public also, to whom so many supplications have been made, have begun to discriminate in favor of him who does not need to advertise. We can but conclude that it is hardly the Code, which is at the bottom of the "hard times" but over-production and over-inducement. As a profession, at least those who are stranded in it have only the redress of restricted immigration since with all the minute divisions into specialties and the fads of multi-millionaires, we can not expect much gratitude and still less recognition. The no-coders say in effect: "It is the public's right and the world owes every man a living; so let none of us withdraw our small talents from the field, but incontinently convert our profession into a trade. We may then peddle our wares from door to door, and perhaps earn a mansion—in the skies."

COST OF IMPURE WATER.

In his "Notes and Comments" on the May report DR. FRANK REILLY, Assistant Health Commissioner of Chicago, says that if a human life is worth \$5,000, as the Legislature of the State of Illinois has decreed, then it is an easy matter to demonstrate beyond any peradventure that the city of Chicago is losing at the rate of more than \$3,000,000 a year through a polluted water supply. His diagrams furnished with the March, April and May monthly reports show, in graphic manner, the sanitary quality of the water and the average daily deaths from the diseases directly affected thereby for a period of twenty-four weeks—from the week ended December 21, 1895 to the week ended May 30, 1896, inclusive. Examination of these diagrams discloses three continuous periods of several weeks each, to-wit, first, from December 21 to January 25—six weeks; second, from February 22 to April 2—seven weeks; third, from April 11 to May 30—eight weeks. During these periods the deaths from the acute intestinal diseases—also shown on the diagrams—were 206, 137 and 258, respectively.

The water supply was "suspicious" or "bad" during the first and third periods, with an aggregate of 464 deaths, or a daily average for the fourteen weeks of 4.7. The water was "usable" or "good" during the intermediate period of seven weeks with an aggregate of 137 deaths, or a daily average of 2.8. The higher death rate of the first and third periods can be attributed to no other cause than polluted water.

Applying to the entire year the figures of the twenty-four weeks covered by the diagrams—probably a sufficiently long period to generalize from—there would be, with a good sanitary quality of water, 365 days \times 2.8 deaths = 1022 total deaths; with a bad sanitary quality of water, 365 days \times 4.7 deaths = 1715 total deaths. Excess of deaths due to polluted water 693, at \$5,000 each = \$3,465,000. This sum represents the interest at 5 per cent. on a capital of nearly \$70,000,000.

"How much of this amount," DR. REILLY asks, "would complete the drainage channel, build intercepting sewers and insure a pure water supply the year around?"

In view of the demonstrated success of water filtration and the progress made in its adoption as set forth in these columns from time to time, the JOURNAL is moved to ask, how much of this amount would be required to establish a filtration system for Chicago which, while furnishing a wholesome water supply for that city, would not transfer its disease and death producing sewage nuisance to its helpless neighbors.

KENTUCKY STATE MEDICAL SOCIETY.

The forty-first annual meeting of this Society was held on June 10, 11 and 12 and was one of the most successful in its history. The meeting was most ably presided over by JOHN A. LEWIS of Georgetown and

the members were most hospitably entertained through the much appreciated efforts of the able chairman of the Committee of Arrangements, DR. R. C. McCHORD, mostly by the residents of the town.

The features of the meeting were the symposium of papers upon subjects chosen by the program committee, upon Bright's disease, vaginal versus abdominal hysterectomy, and fractures. The papers treating of these subjects were interesting and up to date, while the discussion was able and instructive.

The Society puts itself upon record as being opposed to the prevailing practice of criminal abortion and memorialized the State Legislature to pass a statute which will make it possible to punish offenders as there is none now on the statute books which will convict, if the evidence is sufficient. It also, on motion of DR. HENRY E. TULEY, endorsed the resolutions adopted by the AMERICAN MEDICAL ASSOCIATION against the passage of the bill by Congress prohibiting vivisection in the District of Columbia, and requested the representatives in Congress and Senate to use every endeavor to secure its defeat.

On the last day a resolution was passed protesting against the reduction of the fees for Life Insurance examination, and it was learned that Marion County had formed a league among the local physicians and they refused to make an examination for any company for less than five dollars, and it was the sense of the Society that this could be done in all cities as well as the smaller towns.

The committee appointed at the last meeting to "Collect and Codify the Existing Constitution and By-Laws" reported with a new constitution under the belief that it had been appointed to "Revise" the existing constitution. The president ruled that the report was a revision of the constitution and would have to lay over one year before it could be acted upon. The next day it was decided upon motion to "reconsider the motion to delay the discussion of the committee report for one year." This was done and all of the report was adopted except that portion relating to the method of electing officers, which was made to lie over until the next meeting. The Society is still acting under the old constitution, as the author of the motion to "reconsider the vote" was really asking for a reconsideration of the President's ruling which should have been in the nature of an appeal from his decision.

The genial and popular chairman of the Committee of Arrangements, DR. R. C. McCHORD of Lebanon, was the choice of the Nominating Committee for President, and Owensboro was chosen the next place of meeting.

There is hardly any doubt but there will be a change in the method of the election of officers from the present one, the Nominating Committee being chosen by the representatives from the various Congressional

Districts. The new constitution proposes to place the selection of this committee in the hands of the Executive Committee composed of the officers of the Society, but there will be a strong fight made to have the election take place in open meeting as there is so much opportunity under the present and suggested régime for political work and "log rolling."

PAN-AMERICAN MEDICAL CONGRESS.

Gentlemen intending to take part in the meeting of the Second Pan-American Medical Congress to be held in the City of Mexico, residing in Chicago and the Northwest are requested to send their names immediately to the Editor of the JOURNAL of the AMERICAN MEDICAL ASSOCIATION, 61 Market St., Chicago, for transmission to the Mexican Headquarters.

THE BALLOTING.

Several gentlemen have asked if they would be allowed to change their votes before formal announcement. To that we have to say that any member so desiring, should send another ballot properly filled out, marked "*changed*" and properly dated, when, at the counting his original ballot can be found, it will be returned to him.

CORRESPONDENCE.

Proposed Testimonial to Dr. Davis.

ROCKFORD, ILL., June 3, 1896.

To the Editor:—In view of the coming meeting at Philadelphia, which is to celebrate the semi-centennial of the organization of the ASSOCIATION, though still appearing remote, it occurs to me to be none too early now to suggest that an honor, long deferred, though well deserved, be in some commendable way presented through the ASSOCIATION to the medical world, by which our venerable teacher, mentor and friend, Dr. N. S. Davis, the man whose keen and fertile brain, whose prescience ever on the alert for the good of medicine and humanity, originated the plan of the AMERICAN MEDICAL ASSOCIATION, and as constantly and unwaveringly stood by it until its maturity has been attained and all the medical profession of the United States, if not of the civilized world, are ready to rise up and do him homage. Not only has he done this but, with a persistence and courage equally to be commended, he has advanced the standard of medical education, when the espousal meant loss of money and threatened non-affiliation. He lent dignity to the Ninth International Medical Congress, and presided with such evidences of learning and grace as made every American physician proud to own him. Now, when his fifty years of unusually active medical life are rounded out, I believe if the attention of the members of the AMERICAN MEDICAL ASSOCIATION be properly called to it, there can be some tangible recognition of such service given that will be a source of never-failing pleasure to him in his beautifully declining years. Let this be done while his great mind, inured to early toil and serious thought, may be mel-
lowed with a loving and thoughtful deed that will make his pathway strewn with some of the kindlier actions of his admiring brethren in the medical fraternity. No towering shaft or non-corroding bronze can take the place of a loving testimonial tendered him now. He should have been presented with a

general's badge or epaulet with the red cross, after the Ninth International Medical Congress, as well as some recognition of your own untiring service as Secretary General.¹

I think if you will suggest this thought in some suitable way it will not be too early to call attention to it now, and you will be surprised what a universally responsive chord it will strike in the hearts of the profession. Yours, D. L.

Reuben D. Mussey.

NEW CASTLE, COLO., June 8, 1896.

To the Editor:—During my first course of lectures at the Ohio Medical College, 1848-9, R. D. Mussey was Professor of Surgery. He was always kind to his students and patients, though sometimes decidedly brusque with those who had by improprieties brought themselves to grief. As an illustration, a man was placed on the table at the Commercial Hospital with a bubo in either groin. The Professor said: "Young gentlemen, we open these abscesses with a number of small punctures," suiting his action to the word. The patient's hand went involuntarily to the wound with the cry of "Oh God! oh God!" The Professor bluntly said: "Turn over, sir; the way of the transgressor is hard; they that sow to the wind must reap the whirlwind." We open this, you see, in the same way."

Age had made his hand tremulous, and it trembled until the knife touched the desired spot, when it was as steady as in youth.

His lectures were always practical, but extremely terse, never adorned by a single flower.

In the summer of 1849 I went East with Dr. Lyman Beecher, father of Henry Ward, wife and daughter and Dr. Mussey. We crossed Lake Erie on the 4th of July, and at the instance of Dr. Mussey, the passengers invited Dr. Beecher to give us an oration. At Buffalo we parted company with Dr. Mussey, meeting him again at Saratoga and Hanover, N. H., Dr. Beecher and family and myself going to Niagara, Lundy's Lane, and across Ontario to Oswego and so to Saratoga, where we again met Dr. Mussey. Parting company here with these venerable and noble people I went to Caldwell and crossed Lakes George and Champlain to Burlington, and thence by stage via Montpelier to Dartmouth College, where I again met Dr. Mussey and his son, who was a student at Dartmouth. Turning his boy about, he said: "Feel of him; he has never tasted meat."

I suppose all men have their hobbies, and some physicians ride them wildly. Professor Mussey's was diet, well-nigh absolute. After some of his operations he kept the patient for twenty days upon water and three small crackers a day. He was personally very abstemious and for many years a strict vegetarian. He was honest, earnest, a hard student and always a Christian gentleman. In his daily walk and professional life he was a fit exemplar to us all. W. L. SCHENCK, M.D.

The Second Pan-American Medical Congress.

CHICAGO, June 5, 1896.

To the Editor:—To the dignified letter in the May 30 number of the JOURNAL, protesting against the unjust attack on the Mexican people and medical profession, allow me to add my own experiences in support of Dr. Cerna, in the hope that the medical profession in this country may not become prejudiced against our southern neighbors. It would be a pity if any word of hostility to the Mexicans should be the means of reducing the number of those who expect to attend the next Pan-American Medical Congress, because this will undoubtedly be the test meeting, and if it is poorly supported, interest will cease and our relationship with the rest of America will return to the apathy of former years.

¹ A bronze medal was struck, commemorative of this Congress and its chief officers, in 1887.

I have practiced medicine among the Mexicans on terms of greatest intimacy, meeting all classes and finding all degrees of education. I know that Anglo-Saxons are not Mexicans nor Mexicans Anglo-Saxons, but this is a vital reason why it is unjust to study them from one standpoint only. I grant that the percentage of illiteracy is high and superstition consequently more evident, but I failed to find impenetrable stupidity among them, while I did find that the doctor is held in much higher respect than he is in Texas. Next to the priest comes the doctor, and his patient follows the doctor's directions with a strictness that seldom marks the attitude of the patient in this country. Doctors are not nearly so abundant there, and their journeys are often of enormous distances; yet I never found anything but courtesy and hospitality in making my visits, and I was never refused payment for my labor, although my fees were sometimes reduced at the pleadings of the patient.

The National School of Medicine, a part of the University of the City of Mexico, grants degrees entitling the holder to practice throughout the Republic, while a few local schools like that at Monterey can grant this right within the one state only. The result is that the graduate of the National School is a well-posted man, fit to be admitted, as equal, to any medical association in the world; but while the graduate of the local school may be uninstructed in the technique of some of our modern methods, he is always an educated man, able to write his own language and his prescriptions correctly, and fitted to take an honorable place in the society to which his ambition calls him. The Mexican doctor is never ignorant; he may sometimes fail to practice the principles of antiseptics and asepsis, and he may often purge and puke rather briskly in fevers and inflammations, but not every surgeon outside of Mexico avails himself of the principles of his art, nor does every physician in our country abstain from the use of calomel when his diagnosis is doubtful. Above all this, the Mexican physician preserves his dignity, and respects himself and his profession, so that his influence in the community is far greater than is ours at home.

I need say nothing of the morals of the Mexican people. I found them about the same as one finds morals in England, Germany or Spain. But the resident of San Antonio or Chicago had better purify his own social atmosphere before condemning that of his neighbor.

I have purposely generalized my note, but did not space prevent, I could give many an illustration of the courtesy of that people, and of their honor for the man of education, while instances of the very traits criticized in the Mexicans can be found within our borders.

Any one who attends the meeting in the City of Mexico next November will meet with unbounded hospitality, and will return with such broadened knowledge that he will earnestly desire the perpetuity of the Pan-American Medical Congress.

Very respectfully yours,

ALBERT B. HALE, M.D.

The Colorado Ice Decision Not Final.

BUREAU OF HEALTH, DENVER, COLO., June 10, 1896.

To the Editor:—I have noted with some interest the editorial excerpt published in last week's issue of a recent decision of the Colorado Court of Appeals in regard to the limitations of the power of a health commissioner to condemn ice.

Inasmuch as the opinion as rendered is quite misleading and has deliberately ignored, or in some instances contradicts the record as certified in the lower court, and also because the decision as rendered by the court of appeals is not final, the case being now pending in the supreme court of the State of Colorado, I deem it entirely proper to state certain facts in connection with the case which will at least militate against

the acceptance of the decision as rendered as either good law or as justice.

The record as certified showed that the order prohibiting the sale of impure ice was based upon :

1. Repeated analyses of the ice by the bacteriologist of the Denver Health Department and its condemnation by him. Each cubic centimeter was found to produce an average of 40,000 colonies upon the gelatin plates.

2. Repeated analyses of the water of the lake from which the ice was obtained.

3. Sanitary inspection of the lake and demonstration that it was fed by an irrigating ditch which flowed through many manure-covered fields and that it also received direct contamination from sewage. (This may not have been so distinctly brought out in the record as submitted, but the evidence in the lower court was overwhelming.)

4. Conviction in the police magistrate's court after a prolonged hearing covering several days, in which all these points were brought out.

5. Subsequent convictions in the police magistrate's court in at least seven cases where sale of the same contaminated ice for human consumption was proven and the fact of its actual use for human consumption shown beyond possibility of contradiction.

In addition there was pending in the county court at the time the record of proceedings was certified, an appeal, which was prosecuted to a final determination before a jury, resulting in a conviction of the defendant for selling impure ice. Upon this conviction he was fined.

Further, a district court judge, while holding that the sale of such impure ice for storage purposes might not be interfered with, had already issued an injunction restraining the defendant company (the Corbin Ice Company) from selling their ice for human consumption or for use in any place where it might come in contact with human food.

The decision of the court of appeals, ignoring these plain facts which were of record, was received with considerable surprise by the citizens of Denver, especially inasmuch as the defendant company had, through one of its own attorneys, tacitly admitted that their ice was not of a character suitable for human use, and that in selling it as "pure lake ice" they had been doing wrong.

While I do not intend to overstep those bounds which precedent has established as constituting the proper respect to be shown by all citizens for the decisions of the judiciary, I am fain to say that the comment of the decision upon the health commissioner was distinctly improper. The interests of the public are apt to be better safeguarded by the decisions of competent sanitarians, formulated after many months of painstaking investigation and only enforced by the lower courts (as in the present instance) after an impartial consideration of evidence, than by the haphazard decision of any lawyer whom the fortunes of politics or the result of political barter have placed in positions of honor.

As sanitarians work for actual results, it may be of interest to add that no ice from the lake in dispute is being sold in Denver this year for human consumption, nor so long as the responsibility of the enforcement of our present law depends upon me will such sale be permitted. Very respectfully,

WILLIAM P. MUNN, M.D., Health Commissioner.

A Nameless Secret Remedy.

CHICAGO, June 12, 1896.

To the Editor:—In the June 6, 1896, number of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, the agent of an Iowa secret remedy for diphtheria states that Dr. Matter and the consulting physician had pronounced a patient suffering from pneumonia beyond recovery, and that the life of this patient had been saved by the nostrum which he advertises.

As I was the consultant in question, I wish to state that neither Dr. Matter nor myself had pronounced the patient beyond recovery, but merely pointed out the doubtfulness of the prognosis in view of the advanced age of the patient and of the severity of the infection. This is a precaution which no responsible physician will ever omit, and requires no justification. The patient's recovery was such as we see constantly in practice, in illustration of the ability of the human organism to recover from serious illness.

As this bactericide scheme is, in my opinion, a mercenary enterprise under the cloak of philanthropy, it seems unwise to advertise the nostrum even by denouncing it. It would therefore not occur to me to waste any time over it, if physicians graduated from reputable colleges did not stoop to air their "cures" in the newspapers. They give the name, disease and address of their patients, and in most of their reports display such an awkwardness and illiteracy as should make our profession blush both for their effrontery and boorishness.

The agent in question, whom this wily Iowa physician evidently uses as a shield, is waging a warfare against the diphtheria antitoxin, which he is attempting to degrade into a competitive remedy. His method forces the analogy upon me of a drunken man spitting upon a Raphael Madonna. What I therefore wish to protest against is not the character and method of pushing a secret medicine, which is necessarily always dishonest, but the stupidity and recklessness of regular physicians in championing it.

Respectfully,

EDWIN J. KUH, M.D.

Notes on O—a, and the B— C—, with a Few Words on Quackery in General.

CHICAGO, June 15, 1896.

To the Editor:—In my letter of May 2, on Omnicura and the Bracelin cure, I refrained from taking much space in the JOURNAL, because the smallness of the subjects did not warrant it. But in the number of June 6 I find J. J. Russell spreading himself over four columns, ostensibly to answer my criticisms. And there I find that the omnicura has now become a waif and an orphan, disowned and rejected by the very one into whose lap she has poured her golden treasures.

But strange as this may seem, it was his only means for smuggling his letter into print, and use mine as a pretext for sponging a free advertisement out of the JOURNAL. In this he has succeeded as usual and it was necessary that he should. Experience shows that it is difficult to land a shark without giving him plenty of rope and space to flop around in; especially if he is an old one. The same applies to the fresh-water species. These are apt to hold the bait between their teeth, and sulk for three or four weeks at a time, before they start on a run. When they feel the hook they begin to snap with great fury, but being cowardly they can never frighten an honest fisherman. Although worthless when caught, they can be made to furnish excellent sport when properly handled, and before they turn over they invariably try to prove an alibi.

This is just what J. J. Russell, president of the Omnicura Co., and manager of the Bracelin cure has been trying to do by "emphatically stating that there is no more relation or connection between these two, than there is between the Klebs-Loeffler bacillus and the Ferris wheel," wanting to be understood that he is in no wise connected with the omnicura.

The following will prove the value of his statements :

SPRINGFIELD, ILL., June 10, 1896.

MARTIN MATTER, M.D., 3137 Wabash Ave., Chicago.

Dear Sir:—Replying to your letter of June 8. The "Omnicura Remedy Company" was incorporated April 9, 1895, with a capital stock of \$20,000, and the following object: "To manufacture, use and sell 'Omnicura' a new medical discovery." The incorporators were: James J. Russell, Robert E. Buchanan and Hart. J. Fitzgerald. Yours very truly,

W. H. HINRICHSSEN, Secretary of State.

This sample of J. J. truthfulness is not so alarming: but to even grossly slander the Ferris wheel without any use or provocation whatever, shows a very mean disposition.

The letter of thanks which he states the Eppstein family wrote to him, is another myth. He wrote it himself and became so obtrusive to the family that they finally signed it to get rid of him. Any one doubting this may address B. Eppstein, 3144 Wabash Avenue.

No one who is acquainted with the Omnicura will find it strange that J. J. Russell does not want to be connected with this "new medical discovery." Imagine a string or piece of tape, joined at the ends and hanging loosely about the neck, with a number of little plasters attached to it, which are claimed to possess the miraculous power of drawing every known disease out of the system: curing Bright's disease, consumption and every ailment imaginable; this is the Omnicura. The price is \$10 and is based on profound psychologic reasoning. It is well known that a man who is swindled out of a quarter is apt to talk about it; but when the amount is \$10 nothing but silence can keep him from ridicule.

This is the individual whom any physician in this city may meet some day at the bedside of a patient, telling the latter how badly he looks and how hopeless his case is without the Bracelin cure. In one case antitoxin has been used an hour or two before his intrusion—and his nostrum has cured diphtheria when antitoxin had failed. In another a patient is gradually recovering from pneumonia or some other illness—and he was cured by Russell after his physicians had given him up.

Formerly a politician in Iowa, he now uses even physicians as willing or unwilling tools to advertise his nostrum: a fact which must bring a blush of shame to the face of every honest medical man. With overwhelming effrontery he has even brought a mandamus suit against Dr. Reilly, Chief of the Board of Health, because he was refused access to the daily reports of contagious diseases. When a physician resents his impudence he is made an example of in the *Tribune*, by being exposed to public ridicule. The name of Dr. Edwin Kuh, a man of the highest professional standing, is held up to every reader of Russell's pamphlet on the Bracelin cure, as a warning to others who might have the temerity to question its claims, in a letter refilled with new spelling, the main argument being, that Kuh means cow in English.

Quackery will exist as long as there are dupes among mankind, but it must be kept out of contact with legitimate medicine, the quack or his agent is as much out of place in a physician's office or at the bedside of his patients, as a prostitute in the home of a virtuous woman. Our legislation has made enough concessions to mountebanks, without physicians adding thereto. Legalize quackery as such is a well paying business and heeds no encouragement from medical men.

MARTIN MATTER, M.D.

The Wisconsin Diploma Mill.

OFFICE OF ATTORNEY GENERAL,
MADISON, WIS., June 13, 1896.

To the Editor:—Your JOURNAL of April 25 was forwarded to me by one of the good physicians of this State and furnished valuable information to this office for the purpose of bringing an action to dissolve the Wisconsin Eclectic Medical College at Milwaukee.

We have just prepared a complaint and I take great pleasure in forwarding a copy to you. You are at liberty to use it as you see fit. You will notice that I have obtained leave from the Supreme Court of this State to bring an action to annul its charter. This action will be brought in Milwaukee county. I have to-day mailed the papers to the sheriff of that county requesting his service.

Yours truly,

W. H. MYLREA, Attorney General.

STATE OF WISCONSIN, CIRCUIT COURT FOR MILWAUKEE COUNTY.

State of Wisconsin ex re W. H. Mylrea, Attorney General, Plaintiff, vs. Wisconsin Eclectic Medical College, at Milwaukee, Defendant.
The State of Wisconsin, upon the relation of its attorney general, respectfully informs the Court:

That the defendant, the Wisconsin Eclectic Medical College at Milwaukee, is a corporation formally organized and colorably existing under the statutes of this State, and that it was so organized for the nominal purpose of teaching students the science of medicine and preparing and educating them to practice as physicians, and conferring upon them, upon having been examined, and they having succeeded in passing such examinations as to their knowledge of said science, the degree of Doctor of Medicine, or such other degree which might be proper, according to their knowledge exhibited on such examination.

That the date of its supposed organization was on or about the 31st day of December, A. D. 1895, and in the preliminary papers preparatory to organization its principal office and place of business is stated to be in the city of Milwaukee and county of Milwaukee aforesaid.

That heretofore, on the 27th day of May, A. D. 1896, upon the application of W. H. Mylrea, attorney general for the State of Wisconsin, it was by the consideration and judgment of the Supreme Court of said State of Wisconsin ordered that leave and permission be and they were then granted by said Court to said attorney general to commence an action in the Circuit Court of Milwaukee County and State of Wisconsin, upon his relation, against the corporation known as the Wisconsin Eclectic Medical College, to vacate its charter and annul its existence as a corporation, together with such other and further relief as to the Court may seem just and equitable.

And thereupon the State of Wisconsin, by its said attorney general, complaining, shows to the court and alleges:

That on the 23d day of December, 1895, Fred Rutland, Ann Neve Rutland and H. Meyer associated together for the purpose of forming a corporation the object and business of which was stated in the articles of association to be as follows:

1. "For the purpose of teaching students the science of medicine and preparing and educating them to practice as physicians and conferring upon them, upon having been examined, and they having succeeded in passing such examination as to their knowledge of such science, the degree of Doctor of Medicine, or such other degree which may be proper, according to their knowledge exhibited on such examination.

2. "The name of such corporation shall be the 'Wisconsin Eclectic Medical College at Milwaukee,' and its location is in the City of Milwaukee, County of Milwaukee and State of Wisconsin.

3. "This corporation is formed without capital stock.

4. "The general officers of this corporation shall consist of a president, a treasurer and a secretary, the office of secretary and treasurer may be held by one person.

5. "The Board of Directors shall consist of three persons who shall hold their office for five years and shall be elected by the members of the corporation. The Directors shall have the general charge, control and management of the corporation, its affairs and property. The President shall preside at all meetings of the Board of Directors and of the members of the corporation; the Secretary shall preserve the seal, archives and correspondence of the corporation and attend to all business incidental thereto. The Treasurer shall receive and disburse funds of the corporation and shall keep the accounts of the corporation and books belonging to it. Any of these officers may act for the other officer in the absence of the same, and the office of secretary and treasurer may be filled by one person.

6. "Every person of good moral character having a diploma entitling him to practice as a physician may become a member of this corporation by a majority of the vote of the members of this corporation.

7. "Regular meetings of the members of this corporation for the election of directors and for the transaction of other business shall be held annually on the first Tuesday after the first day of January of every year.

8. "The signers of these articles are at the time of the signing thereof the only members of the corporation, and the first meeting of the members thereof for the purpose required by law shall be held at Room 7 of Lipp's Block, City of Milwaukee and County of Milwaukee, on the 27th day of December, 1895, at 3 o'clock in the afternoon."

Said articles were signed by Fred Rutland, Ann Neve Rutland and H. Meyer, on the said 23d day of December, 1895, recorded in the office of the Register of Deeds for Milwaukee County, and on the 31st day of December, 1895, duly filed in the office of the Secretary of State of said State of Wisconsin.

Complainant further complaining denies that he has any knowledge or information sufficient to form a belief as to whether or not a Board of Directors for said corporation has ever been elected, or as to whether or not the person "H. Meyer," one of the alleged signers of said articles of incorporation, has any existence in fact.

Complainant alleges upon information and belief that no record has been kept of the meetings of the Board of Directors of said corporation, if it has a Board of Directors, and that no by-laws have been adopted by said corporation, and that no record of any of the acts or doings of said corporation has been kept or preserved in any manner. That said corporation pretends to be carrying on the business of a medical college at 1809 Fond du Lac Avenue, in the City of Milwaukee, Wisconsin, in certain rooms above a store building located at that place, which rooms are adapted for residence purposes only and are utterly unfit for the purpose of the business of carrying on a medical college. That said corporation has no apparatus or paraphernalia of any kind suitable for the carrying on of a medical college, or for the giving of instruction therein. That it has no medical library of any kind suitable for the use of teachers or students. That it employs no teachers to give instruction to persons desiring to obtain a medical education. That it has never exercised the rights and privileges intended to be conferred upon it by its articles of organization, and does not intend to exercise any of the rights and privileges so intended to be conferred upon it.

Complainant further alleges upon information and belief that said Fred Rutland, Ann Neve Rutland, the wife of said Fred Rutland, and said H. Meyer, if there be a person by that name, did not organize said corporation in good faith for any of the purposes mentioned in its said articles of organization, but fraudulently and unlawfully organized said corporation for the sole purpose of enabling them to issue to ignorant and unskilled and wholly incompetent persons, spurious and bogus diplomas purporting to confer upon such persons the pretended authority of practicing medicine and surgery with intent thereby fraudulently to procure from such persons large sums of money in payment thereof.

Complainant further alleges upon information and belief that after said association had thus been formally organized in accordance with the laws of this State, the said Fred Rutland and Ann Neve Rutland, his wife, in furtherance of the unlawful and fraudulent scheme aforesaid,

procured from the Secretary of State of said State a certificate such as he is required by law to issue, certifying that there had been on the 31st day of December, 1895, filed in his Department "an instrument in writing, purporting to be articles of association of a corporation to be known as the Wisconsin Eclectic Medical College at Milwaukee, without capital stock," the business and purposes of which was to conduct a medical college, etc., and that, therefore the State of Wisconsin did certify and grant unto the said Wisconsin Eclectic Medical College at Milwaukee, the powers and privileges conferred by Chapter 66 of the Revised Statutes of the State of Wisconsin, and all acts amendatory thereof, for the purposes above stated, and in accordance with their said articles of association."

In witness whereof the said Secretary of State affixed his hand and official seal on the said 31st day of December, 1895.

Complainant further alleges upon information and belief that thereafter Fred Rutland and Ann Neve Rutland, for the purpose of carrying out their fraudulent scheme as aforesaid, caused a large number of advertisements to be inserted in newspapers throughout this and other States, and a large number of circulars soliciting persons to apply to it for diplomas and licenses such as would permit them to practice medicine and surgery in this and other States, said advertisements and circulars among other things stating in substance that if the applicant should be able to answer before a notary public of his own town certain questions to be submitted by said corporation, and upon the payment of a fee prescribed by said corporation, that said corporation would issue a diploma to such persons, which diploma would enable such persons to practice medicine in this and other States of the Union, and in proof of its authority to issue such diploma, and for the purpose of inducing persons to act upon these statements, said Fred Rutland and his wife would send out with such circulars a copy of the certificate issued by said Secretary of State, as aforesaid, and would further allege in said circulars that the State of Wisconsin had satisfied itself that the purposes of the corporation were regular and in accordance with the law, and had accepted a fee for incorporation and affixed its seal to the charter of said corporation, which charter declared the purposes and methods of the corporation, and that the State thereby had sanctioned such purposes, and that therefore no person or power could disturb either said college or its graduates.

That by means of the authority apparently conferred upon said corporation by its articles of incorporation and through said advertisements and said circulars the said Fred Rutland and wife have induced a great many persons to apply to them for and to pay them considerable sums of money for such diplomas, and have issued a great many of such diplomas to such persons, who have made no preparation or study of either the science of medicine or surgery, and who are wholly unfit and incompetent to practice either the science of medicine or surgery.

Complainant denies that he has any knowledge or information sufficient to form a belief as to how many of such diplomas have been issued, but alleges that a large number of them have been issued, and that Fred Rutland and Ann Neve Rutland, his wife, have by the means aforesaid fraudulently procured considerable sums of money, the exact amount of which complainant is unable to state, but he alleges upon information and belief that said Fred Rutland and wife have received for each of said diplomas a sum varying from \$15 to \$60, according to the ability of the applicant to pay for the same.

Complainant alleges upon information and belief that not only was said corporation organized as aforesaid solely for the purpose of enabling its incorporators to carry on the fraudulent business above described, but that said fraudulent business above described is now and will continue to be its only business so long as said corporation shall be permitted to exist.

That the carrying on of said business is detrimental to the advancement of the science of medicine and surgery, as well as contrary to good morals and public policy. That it directly tends to encourage ignorant, unscrupulous and wholly unfit persons to practice the important professions of medicine and surgery, thereby greatly endangering the welfare and good health of many of the people of this State.

In short, that the carrying on of said business by said corporation is clearly a wilful misuse and abuse of the privileges and franchises conferred upon it by its articles of incorporation.

WHEREFORE, Complainant prays the Court that it will vacate the charter and annul the existence of the said Wisconsin Eclectic Medical College at Milwaukee, together with such other and further relief as to the Court may seem just and equitable.

Medical Society of State of Pennsylvania.

HARRISBURG, PA., June 15, 1896.

To the Editor:—In your issue of May 30, page 1092, it is stated the "next convention will be held at Pittsburg in September, 1897." The next meeting of the Medical Society of the State of Pennsylvania will be held in Pittsburg, Pa., the third Tuesday of May, 1897. There was some mention of September, but May is provided for in the By-Laws. Convention is not a good word to use for meetings of medical men, though a good many journals use it, our JOURNAL should set a better example. The above correction of date and title is so you can have the list of meetings correct. Very truly,

W. T. BISHOP, M.D.

The Journal Itself.

NEW CASTLE, IND., June 5, 1896.

To the Editor:— . . . It is the best medical journal published, the best the Association has ever had, and improving weekly.

G. W. BURKE, M.D.

LIBERTY, MO., June 14, 1896.

To the Editor:—Allow me to compliment the JOURNAL as one of the best in the United States.

J. M. ALLEN, M.D.

CHICAGO, June 6, 1896.

To the Editor:—In enclosing my vote, I take pleasure in asking to be allowed to thank you for your good work on our JOURNAL. I think it is the high-class weekly for the general profession in the United States. Cordially yours,

ALBERT B. HALE, M.D.

CLYDE, N. Y., June 12, 1896.

To the Editor:—With great pleasure I acknowledge the receipt of my much wished for copy of the JOURNAL of Dec. 28, 1895. I am more than ever tenacious that there shall be no break, as, without flattery, under the present editorial conduct, it is a library of itself, and the best medical journal now published.

I assume to be a competent judge, as I have been a reader of it since its first publication in the weekly form.

Yours truly, D. COLVIN, M.D.

CINCINNATI, June 5, 1896.

To the Editor:—I enclose to you my ballot, as also my check for \$5 for yearly dues.

Now, my dear Doctor, I want to thank you for your distinguished services as Editor of the JOURNAL. I think it ranks with the journals of the East.

The tone of the JOURNAL is high. It firmly supports the Code. In my opinion, it will grow and grow, and show the world that no section can control the Western and Southern profession. Wishing you and the JOURNAL all success, I am

Yours truly, JOHN A. MURPHY, M.D.

PUBLIC HEALTH.

Dr. Bond of Gloucester, Eng., sends us a copy of a useful leaflet drawn up by him and entitled "Our duty in regard to Vaccination, or fifteen reasons why we should believe in the efficacy of Vaccination as a Preventive of Smallpox." This might be distributed broadcast in those districts where recalcitrant Board of Guardians have failed to do their duty.

Low Sickness-Rate in the German Army.—It is pleasant now and then to put one's finger on a fact that sustains faith in the application of hygienic measures. The General Staff Surgeon of Prussia reports that by the energetic application of hygienic measures—which include vaccination and revaccination—the invaliding among troops has been reduced 42 per cent. since 1868, and the mortality has been lessened 57 per cent., which means that two thousand men were alive at the end 1895 who would not have been had the former conditions obtained.

Schools and Disease; A Model Preventive System.—Dr. Leslie McKenzie, the Health Officer for the Borough of Leith, refers in his annual report for 1895 to the system followed in the town for the better prevention of the spread of infectious disease by the agency of schools. Each day an official of the School Board of Leith calls upon the health officer for the purpose of receiving lists of infectious cases notified to him, and then proceeds to distribute particulars to the different masters whose schools are interested in the cases, with the view of at once securing the absence from school of all children from an infected house until the house has been declared to be disinfected, etc., to the satisfaction of the health officer or some medical practitioner. Headmasters also notify to the School Board all cases of sickness coming to their knowledge, and thereupon similar steps are taken. The system is modeled on that obtaining at Glasgow, and gives satisfaction. Given the strict carrying out of the plan it ought to succeed.—*British Medical Journal*.

Annual Death Rate in Peru.—Odriozola's address at the Commencement of the University at Lima, contains the statement that the annual death rate at Peru is from 35 to 40 per thousand, of which a third is due to tuberculosis, while many of

the rest, and an immense proportion of the ills, are due to alcoholism in its effects on generation after generation. As the population of Peru is so small he urges that the very existence of the nation, to say nothing of other reasons, demands the improvement of this state of affairs. Special institutions should be established for the tuberculous poor, one in the mountains and one at the seashore, which might save many lives now doomed, while preventing the infection of countless others. The climate of Peru is peculiarly healthful, and careful sanitation might make it the most favored spot on the globe instead of its present record of elevated mortality.—*El Monitor Medico*, May 1.

The Prevention of Caisson-Disease.—According to the *Medical News* the prophylaxis of this affection, or chain of symptoms, has been the subject of experimental investigation in France. M. Hersent, a civil engineer, expresses the firm conviction that the large sacrifice of life in the past has been due to the rapid variations in the degree of compression brought about by ignorance or carelessness. He found that dogs could endure, without danger, a pressure of seventy-five to eighty pounds to the square inch for as much as five hours, provided that twenty-five minutes were occupied in gradually producing this amount of compression and one and a half hours in "decompression," a uniform temperature being maintained. Practically the same experiments, with perhaps a more gradual change in the pressure, were carefully made upon workmen, with only a little lassitude, lumbago, and slight prickling sensations of the surface resulting. It was thus demonstrated that without overtaxing the workmen they can labor uninterruptedly for four hours or more under a pressure of seventy-five pounds or more; that is to say, at 150 to 175 feet below sea level, on condition that they should experience a very slow compression and "decompression," and that the temperature be uniformly maintained.

The Identity of Diphtheria in Man and the Lower Animals.—The *British Medical Journal* quotes from the article on the above subject, by Dr. Leon Gallez, of Chatelet, in the *Bulletin de l'Académie Royale de Médecine de Belge*. The writer states that the bacterial proof of the non-identity of the diphtheric organisms found in man and the lower animals, such as the pigeon, chicken, calf, rabbit, cat, dog, horse and pig, is not conclusive. On the other hand, the numerous observations of the transmission of the disease from man to the lower animal, nine cases being cited from the literature upon this subject, and vice versa, seventy-two observations, are considered by Gallez to be almost positive proof of the identity of the different organisms which have been described in connection with diphtheria in man and the lower animals. Four histories are also given in which the transmission of human diphtheria to an animal has been in return followed by its recommunication to man. While the morphology is different, it is not more so than can be explained by the variations of the Klebs-Löffler bacillus as seen upon different culture media, likewise the symptomatology differs on account of the various anatomic peculiarities of the different species of animals in which the disease occurs. The author considers that we have in animals both an accidental form and an habitual one, the latter being merely a repetition of the culture of successive generations in the individual of the same species, the organism finally taking on special characteristics.

Salutary Influence over Medical Education of a National Board of Examiners. An editorial in the *Public Health Journal*, May, presents the following argument on behalf of a National Department of Health: During the last few years nearly all the States of the Union have passed stringent laws with a view to regulate the practice of medicine, abolish quackery and elevate the standard of medical education, and in order to test the qualifications of physicians proposing to practice, examining

boards have been created. In many of the States having such boards no weight whatever is given to the fact that a physician who may wish to locate in such State already has a diploma from some medical college of high standing; that he may have already honorably passed the examining board of some other State, and has been perhaps for many years a successful or even eminent practitioner; he must be again examined by the State board to which he desires to remove. These matters are regulated much better in France, and, we believe, in other European countries. When a student has passed his examination before any of the French medical faculties, his diploma is indorsed by the government; that done, he has a right to practice his profession wherever the tricolor flies. The cumbersome and unjust methods adopted by the several States in licensing physicians to practice should be terminated with as little delay as possible. We are of the opinion that the various State medical societies should co-operate to formulate plans for the creation of a National Examining Board, which should have the power to examine physicians and grant certificates to practice, valid in any part of the United States, as well as to indorse the certificates of State boards, thus rendering them universally valid in this country without further inquiry.

Cause of Death Following Serum Injections.—A most interesting series of experiments have been made by Drs. A. Siebert and F. Schwyzer of New York City, with a view of determining the cause of sudden death following the injection of antitoxic serum. Their processes, results and conclusions form the subject of a paper read before the American Pediatric Society at its meeting in Montreal, May 26, ult. The scope of the experiments had reference to: 1. The possibility that the serum itself might do the killing, either by entering the circulation too rapidly and in too large a quantity by an opened vein, or by poisonous substances having formed in the antitoxin in consequence of decomposition. 2. The possibility that the carbolic acid used in preserving the serum was the cause of death. 3. The possibility that death is caused by the injection of air into the blood current with the serum.

The experiments made to determine these three possibilities seem to have been made, judging by the detailed accounts, with due care and thoroughness and upon them the authors base the following statements and conclusions: "1. Antitoxic serum does not seem to be capable of causing threatening symptoms and speedy death, even when brought quickly into the blood current in very large doses. 2. The carbolic acid used in preserving the antidiphtheritic serum must be in such a weak solution as to be entirely unable to cause the characteristic carbolic convulsions produced in every one of our second series of experiments. The absence of these convulsions in the cases of sudden death in patients, the entirely different group of symptoms reported in them and the fact that guinea pigs and rabbits will survive even very large and concentrated doses of carbolic acid injected into a vein, lead us to discard the possibility of this drug having caused the reported deaths. 3. Ever very small quantities of air caused severe disturbances and ultimate cessation of breathing in every animal experimented upon. These disturbances are entirely analogous to the symptoms reported as preceding the sudden deaths after antitoxin injections. Air is found alongside of the fluid in every syringe used for hypodermic injections, and being pressed under the skin with the fluid may readily come in contact with a punctured cutaneous vein and so may enter the blood vessel and the right heart, even before the serum has been absorbed. "In view of these facts and of our experiments, we here express our firm opinion that the sudden deaths reported after antitoxin injections were caused by injected air and not by antidiphtheritic serum." This conclusion would be more forcible if the fact were stated that in ordinary hypodermic injections of other substances instances of sudden death have been

uncommon as altogether to escape notice. Every practitioner we believe invariably excludes the air from the syringe before making the injection. Is it supposed that his practice changes when using antitoxin?

A New Anti-tetanus Serum.—The following circular of the New York City Board of Health shows the enterprise and industry of the bacteriologists of that Board:

"The New York City Health Department is prepared to furnish antitoxin serum for the treatment of tetanus. Each vial contains 20 c.c. of serum, having an immunizing power of 1 to 3,000,000; i.e., 1 c.c. of serum protects 3,000,000 grams of guinea pigs in weight from a fatal dose of tetanus toxin. The average initial dose of the serum varies with the gravity of the case and the time when treatment is begun. The remedy is administered by deep hypodermic injections, a large syringe (such as has been employed for diphtheria antitoxin) being preferably employed for the purpose, although an ordinary hypodermic syringe carefully cleaned may be used, the barrel of the syringe being repeatedly filled. Some point on the anterior surface of the body should be chosen for the injection, where there is an abundance of subcutaneous cellular tissue, as the anterior surface of the abdomen or thorax or the outer surface of the thigh. Before the remedy is administered the skin should be carefully washed with some disinfecting solution, and the syringe carefully sterilized and then washed with sterilized water. The solution is rapidly absorbed and it is better not to employ massage over the point of injection. It is of vital importance in tetanus that the antitoxin be administered at the earliest possible moment, as the dose required to neutralize the tetanus toxin absorbed increases with great rapidity with each hour's delay. When the treatment is begun at the first appearance of tetanic symptoms and they do not point to a very severe infection, and especially when the incubation period has been long, e.g., two weeks; one vial, or 20 c.c., may suffice for the first injection, and, according to the results, one-half the quantity or the same quantity should be repeated at intervals of from six to twelve hours during the four following days. If the infection is intense, as shown by a short incubation period, e.g., five to eight days; or by the rapid development of the tetanic symptoms and by the predominance and intensity of bulbar phenomena, or if the treatment is begun several days after the appearance of the tetanic symptoms, even if at the time of injection they are not severe, the contents of one vial should be at once injected, and the dose repeated at short intervals, according to the effect produced on the tetanic symptoms. The doses required where the wound has been previously untreated, even if the symptoms are slight, are usually large. The dose for children under twelve should be one-half or less than that for an adult. The use of tetanic antitoxin does not preclude the employment of other remedies, such as chloral, the bromids, physostigmin or morphin. Some one or more of these remedies should be employed in full doses. It is also thought to be advantageous to give large amounts of water to the patient for its diuretic effect, as the tetanus toxin is eliminated by the kidneys. Where tetanus follows some wound of the surface, this should be treated freely with some preparation of iodine in solution, to destroy the toxins in it. The ordinary antiseptic solutions, such as carbolic acid and bichlorid of mercury, are of little value for this purpose. The exact value of tetanus antitoxin in the treatment of this disease and the best method of administration have not been fully determined and the Health Department of the city of New York especially requests that all persons using this preparation of antitoxic serum will forward a full report to the Department of the case and the results of treatment. All public institutions in New York City, on application, will be furnished with tetanus antitoxin free of charge.

"Approved by the Board of Health at a meeting held May 19, 1896. EMMONS CLARK, Sec'y; CHARLES G. WILSON, Pres.

"Address The Bacteriological Laboratories, Health Department, Criminal Court Building, Center, Elm, White and Franklin Streets. Telephone, 448 Franklin."

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon-General, U. S. Marine-Hospital Service:

SMALLPOX (UNITED STATES).

Louisiana: New Orleans, May 31 to June 6, 4 cases, 1 deaths.

SMALLPOX (FOREIGN).

Birmingham, Eng., May 23 to 30, 2 cases.

Bombay, India, April 28 to May 12, 58 deaths.

Buenos Ayres, Brazil, March 1 to 31, 24 deaths.

Calcutta, India, April 25 to May 2, 1 death.

Callao, Peru, May 3 to 17, 13 deaths.

Genoa, Italy, May 23 to 30, 1 case.

Guayaquil, Ecuador, May 15 to 30, 7 deaths.

Licata, Italy, April 16 to 23, 3 deaths.

Madrid, Spain, May 19 to 26, 10 deaths.

Naples, Italy, May 23 to 30, 4 cases, 1 death.

Odessa, Russia, May 11 to 23, 7 cases, 4 deaths.

Pernambuco, Brazil, April 1 to 30, 55 deaths.

Prague, Austria, May 16 to 23, 6 cases.

Rotterdam, Holland, May 23 to 30, 1 case.

Tuxpan, Mexico, May 16 to 23, 3 deaths.

Warsaw, Russia, May 9 to 25, 4 deaths.

CHOLERA.

India: Bombay, April 28 to May 12, 31 deaths; Calcutta, April 25 to May 2, 252 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, May 2 to 9, 38 deaths; Pernambuco, April 1 to 30, 8 deaths.

Buenos Ayres, March 1 to 31, 5 deaths.

Cuba: Havana, May 28 to June 4, 9 deaths.

ASSOCIATION NEWS.

Notice.—Members of the ASSOCIATION desiring to attend the Second Pan-American Medical Congress at Mexico in September, as delegates to that body, will please address the Permanent Secretary, William B. Atkinson, M.D., 1400 Pine Street, Philadelphia, Pa., for their credentials.

Section on Materia Medica, Pharmacy and Therapeutics.—*To the Editor:*—Enclosed please find copy of resolutions passed by the Section on Materia Medica, Pharmacy and Therapeutics, AMERICAN MEDICAL ASSOCIATION, at Atlanta, Ga., May 7, 1896, in regard to a paper on "Anti-Phthisin," read by Dr. Ambler.

Dr. Stewart has written you in regard to it. I also enclose the address of Professor Klebs, delivered on the same subject.

Yours truly, W. B. HILL, M.D.

Milwaukee, Wis., June 11, 1896.

The Committee beg to report as follows:

That Dr. Klebs disclaims any knowledge that Anti-Phthisin is a proprietary remedy, although he admits having heard that the name was copyrighted in Germany, and that he has heard that application for the same has been made in this country.

We also find that all rights to this remedy have been transferred to Karl von Ruck, and therefore find that it does come in under the head of proprietary medicines, and respectfully refer the publication of the paper to the Business Committee for their consideration.

WHEREAS, The AMERICAN MEDICAL ASSOCIATION'S Code of Ethics has declared its opposition to secret remedies and refuses to be used as a body, and through its official organs, to further the interests of any and all patent medicines; and

WHEREAS, Dr. C. P. Ambler, Associate Medical Director and Laryngologist of the Winyah Sanitarium of Asheville, N. C., representing and defending the Klebs Anti-Phthisin before the ASSOCIATION and also Dr. Karl von Ruck, the controller of this product, has declared before the Section on Materia Medica, Pharmacy and Therapeutics, that it is true that Klebs Anti-Phthisin is protected by copyright and that a patent has been applied for both in this country and Germany, to restrict its production for the benefit of the owners of the patent.

Resolved, That a committee of three be appointed to investigate the matter without delay, and report its finding to the proper officers of this ASSOCIATION and in the columns of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Resolved, further, That the Committees on Ethics and Publication and such other committee as the Chairman of the Section may deem fit, shall take cognizance of the matter and take such steps as may be considered necessary to prevent the prostitution of this ASSOCIATION and of its JOURNAL for the advancement of this remedy if found excluded by the rules and laws of medical ethics, and shall publish their finding in said JOURNAL.

SOCIETY NEWS.

Chicago Medico-legal Society.—At the last meeting of this Society the following officers were elected to serve for the ensuing year: President, Dr. E. J. Doering; first vice-president, Dr. Sanger Brown; second vice-president, Dr. A. H.

Cooke: treasurer, Dr. Jos. Matteson: secretary, Dr. John Ridlon, 103 State Street.

Washington State Medical Society.—At the annual meeting of this society held in Tacoma May 19 and 20, Dr. R. L. Thomson, of Spokane, was elected president, and Dr. J. M. Semple, of Medical Lake, Secretary. The next meeting will be held in Spokane, May 1897.

Nebraska State Medical Society.—At the annual meeting the following officers were elected for the ensuing year: President, F. D. Haldeman, Ord; first vice-president, J. Lue Sutherland, Grand Island; second vice-president, O. Grothan, St. Paul; recording secretary, G. H. Simmons, Lincoln; treasurer, W. M. Knapp; corresponding secretary and librarian, H. B. Lowry, Lincoln. The next annual meeting will be held in Lincoln.

Veterans of Indian Wars.—The latest society with military features is the Society of Veterans of the Indian Wars. Article 3 of the constitution provides that any past or present officer or acting officer, non-commissioned officer or soldier of good moral character and reputation, who has served in the army of the United States during an Indian war, and who has actually been in service in the country occupied by hostile Indians, and whose services terminated honorably and who can furnish suitable certificate as to such services, is entitled to active membership. No honorary membership is permitted. Dr. W. T. Parker, Groveland, Mass., will furnish information on this subject to those who desire it.

Association of Life Insurance Medical Directors.—The following are the officers of the Association for 1896-7: President, Edgar Holden, M.D., Newark, N. J.; first vice-president, H. Cabell Tabb, M.D., Richmond, Va.; second vice-president, J. H. Webb, M.D., Waterloo, Ont.; secretary, O. H. Rogers, M.D., New York City; treasurer, John W. Brannan, M.D., New York City; executive committee, Drs. Edward Curtiss, New York City, Abel Huntington, New York City, G. R. Shepherd, Hartford, Conn. and Albert Wood, Worcester, Mass. Dr. J. W. Fisher is chairman of a special committee on collective investigation on accurate statistics on certain kinds of impaired lives and Dr. E. H. Hamill is chairman of a committee on research as to impaired family history.

Mississippi Valley Medical Association.—A meeting of the Executive Committee of this association was held at Atlanta, on May 6, and the following gentlemen were appointed to deliver addresses: Dr. H. N. Moyer, Chicago, address on medicine; Dr. Horace H. Grant, Louisville, address on surgery; the indications are that the meeting to be held at St. Paul, on October 20, 21, 22 and 23, will be the largest and most successful in the history of the association. As all the railroads will offer reduced rates for the round trip, an opportunity will be given to visit St. Paul and Minnesota during the most delightful season of the year. H. O. Walker, M.D. Detroit, Mich., president; H. W. Loeb, M.D., 3559 Olive Street, St. Louis, secretary; C. A. Wheaton, M.D., St. Paul, Minn., chairman committee of arrangements.

The American Medico-Psychological Association. According to the *Boston Medical and Surgical Journal*, May 28, the fifty-second annual meeting of the Association, held in Boston during the last week in May, has been largely attended. An address of welcome was made to the society by Governor Wolcott, and the President, Dr. Richard Dewey, delivered an address on "Our Association and Our Associates." At the afternoon meeting papers were read by Dr. Theodore W. Fisher of Boston, Dr. W. Worcester of Danvers and Dr. Henry J. Berkeley of Baltimore. An evening session was held at the Hotel Brunswick, the headquarters of the Association, on which occasion there were given addresses by Dr. R. M. Burke of London, Ont., Dr. Joseph G. Rogers of Logansport,

Ind., and by Dr. E. N. Brush. On Wednesday morning the annual election of officers took place, and in the afternoon the members, with ladies, were given a lunch at the McLean Hospital in Waverly. In the evening a reception was given to the members by the Boston Medico-Psychological Society at the University Club.

Concerning Antivivisection.—The American Laryngological Association, in annual session at Pittsburg, Pa., May 15, 1896, by unanimous vote, and by appended signatures of its officers and members of committee, hereby records its most earnest and emphatic protest against such legislation as that proposed by the bill entitled, "A bill for the further prevention of cruelty to animals in the District of Columbia," Senate bill 1552, in so far as this legislation embodies measures intended to control and restrict experimentation upon animals conducted in the government laboratories, the medical schools and other institutions of higher learning in the District of Columbia. In making this protest the Association begs to present to the members of Congress the following considerations: Animal experimentation has proved itself by years of usage, the most important and indispensable method of arriving at conclusions concerning the functions of, and the influences which modify or develop, all living organisms. All the greater advances which have been made in the science and art of medicine in recent years have been based, to a great extent, upon such experiments upon the lower animals, especially as conducted in the laboratories of the Government, and in other scientific institutions. These advances would, in fact, have been impossible without such aid. The untold benefit which mankind has derived, and will continue to receive, from these advances, need not be further detailed than to mention the inestimable boon conferred by the discovery and development of the antitoxin treatment of diphtheria, the inoculation for rabies, the detection for tuberculosis in animals, and the consequent lessening of its spread among human beings. The revolutionizing of surgical practice and the success attending the major operations by the introduction of antiseptic measures have been brought about chiefly through animal experimentation. The benefits derived from these experiments largely go to improve public health and prevent infectious diseases. This fact is often overlooked by the laity. J. H. BRYAN, M.D., Chairman of Committee; WILLIAM H. DALY, M.D., President; H. L. SWAIN, M.D., Secretary.

Ontario Medical Association.—This Association met at Windsor, Ont., June 3 and 4. President, F. LeM. Grasett, Toronto. The following papers were read: "The Treatment of Puerperal Sepsis," by H. T. Machell, Toronto; "The Operative Treatment of Mammary Carcinoma," by W. Burt, Paris; "The Preservation of the Perineum in Labor," by C. B. Oliver, Berlin; "Neurasthenia," by E. E. Harvey, Norwich; "Pregnancy Complicated with Retroversion—a Case," by Alex. Bethune, Seaforth; "Broncho-pneumonia," by A. E. Harvey, Wyoming; "Hemoptysis," by J. M. Cotton, Lambton Mills; "Movable Kidney and Another Way of Anchoring It," by F. B. Wilkinson, Sarnia; "Treatment of Abortion," by G. McKeough, Chatham; "Skin Grafting," by R. Whiteman, Shakespeare; "Glioma of the Brain," by A. J. Johnson, Toronto; "Roentgen Photography and Its Application to Medicine and Surgery, with Exhibition of Apparatus and Demonstration," by Edmund E. King, Toronto; "The Rational Treatment of Typhoid Fever," by J. P. Armour, St. Catharines; "Treatment of Phthisis," by W. B. Geikie, Toronto; "Phthisis as a Factor in the Causation of Insanity," by E. H. Stafford, Toronto; "Absorbable Ligature in Abdominal Surgery," by M. V. Mann, Buffalo, N. Y.; "Mixed Infection," by J. Caven, Toronto; "Missed Abortion," by F. R. Eccles, London; "The Total Stamping out of Transmittable Diseases," by A. Groves, Fergus. The following officers were elected: President, Dr. John Coventry, Windsor; First Vice-President, Dr. F. R. Eccles, London; Second Vice-President, Dr. Clark, Kingston; Third Vice-President, Dr. H. T. Machell, Toronto; Fourth Vice-President, Dr. J. C. Armour, St. Catharines; General Secretary, Jno. N. E. Brown, Toronto; Assistant Secretary, E. H. Stafford, Toronto; Treasurer, Geo. H. Carveth, Toronto. The next place of meeting is Toronto, Ont.

Indiana State Medical Society.—The following resolutions were unanimously adopted by the Indiana State Medical Society at Ft. Wayne, May 28, 1896, as presented by Dr. E. L. Larkins of Terre Haute.

WHEREAS, A bill is now pending before Congress known as Senate Bill No. 1552 entitled "A bill for the further prevention of cruelty to animals in the District of Columbia;" and

WHEREAS, Such a bill is an unjust reflection upon the humanity of the members of the most humane and charitable profession in the world, and especially against those engaged in experimental work; and

WHEREAS, The passage of such a bill for the District of Columbia would only serve as a nidus for its spread to other States; therefore, be it

Resolved, That the Indiana State Medical Society hereby indorses the report of the Committee on Vivisection of the AMERICAN MEDICAL ASSOCIATION and adopted by that body at the recent meeting in Atlanta; and be it further

Resolved, That the secretary be and is hereby instructed to immediately furnish each member of Congress from this State (House and Senate) a copy of this preamble and the resolutions, properly signed by the president and secretary under seal of the Society, together with a copy of the above named report, instructing them to oppose the action of the so-called Humane Society of the District of Columbia.

F. C. HEATH, M.D., Secretary.

Indianapolis, June 16, 1896.

BOOK NOTICES.

A Text-Book of Bacteriology. By GEORGE M. STERNBERG, M.D., LL.D., Surgeon General U. S. Army. Illustrated by heliotype and chromo-lithographic plates and 200 engravings. Cl., 8vo, pp. 693. New York: William Wood & Co. 1896.

This book is really a revision of the well-known Manual by the same author, published in 1892. The author says in the preface: "For the benefit of students of medicine and others who do not care especially for the detailed descriptions of non-pathogenic bacteria and the extensive bibliography contained in the Manual, this Text-Book of Bacteriology is now published. It comprises that portion of the Manual above referred to as printed in large type, revised to include all important additions to our knowledge of the pathogenic bacteria since the original date of publication." This is an honest revision and the reader will have cause to complain of few if any omissions. The same modesty has characterized the author's statements in this work in all matters concerning his own discoveries as in the Manual. With regard to the phagocytic action of the white corpuscles, he thus mentions his own clear priority over Metchnikoff: "Now the theory of phagocytosis assumes that the bacilli are picked up by the leucocytes and destroyed in their interior, and that immunity depends largely upon the power of these phagocytes to capture and destroy living pathogenic bacilli. The writer suggested this as an hypothesis as long ago as 1881, in a paper read before the American Association for the Advancement of Science in the following language: 'It has occurred to me that possibly the white corpuscles may have the office of picking up and digesting bacterial organisms which by any means find their way into the blood: the propensity exhibited by the leucocytes for picking up inorganic granules is well known, and that they may be able not only to pick up but to assimilate and so dispose of the bacteria which come in their way does not seem to me very improbable in view of the fact that amebæ, which resemble them so closely, feed upon bacteria and similar organisms.' At a later date (1884) Metchnikoff offered experimental evidence in favor of this view, and the explanation suggested in the above quotation is commonly spoken of as the Metchnikoff theory." He then quotes Metchnikoff extensively as showing the details of phagocytic action and refers to recent contradictory statements as follows, p. 257: "Numerous experiments have been made during the past two or three years with a view to determining whether pathogenic bacteria are, in fact, destroyed within the leucocytes after

being picked up, and different experimenters have arrived at different conclusions. In the case of mouse septicemia, already alluded to, and in gonorrhea, one would be disposed to decide, from the appearance and arrangement of the pathogenic bacteria in the leucocytes, that they are not destroyed, but that on the other hand, they multiply in the interior of these cells, which in the end succumb to this parasitic invasion. In both of the diseases mentioned we find leucocytes so completely filled with the pathogenic microorganisms that it is difficult to believe that they have all been picked up by a voracious phagocyte, which has stuffed itself to repletion, while numerous other leucocytes from the same source, and in the same microscopic field of view, have failed to capture a single bacillus or micrococcus. Moreover, the staining of the parasitic invaders, and the characteristic arrangement of the 'gonococcus' in stained preparations of gonorrheal pus indicate that their vitality has not been destroyed in the interior of the leucocytes or pus cells, and we can scarcely doubt that the large number found in certain cells is due to multiplication *in situ* rather than to an unusual activity of these particular cells. . . . We can not consider this question as definitely settled." The author then quotes Metchnikoff's views in full. The Americans may congratulate themselves that the ablest and most comprehensive text-book on bacteriology in the English language has been given to the world by one of their own countrymen. The publisher has done his part of the work with the uniform excellence which is characteristic of the house.

Typhoid Fever and Its Abortive Treatment. By JOHN ELIOT WOODBRIDGE, M.D. Copyrighted. Cl., 8vo, pp. 368. Price, \$3. Cleveland, Ohio: L. Leavengood & Company. 1896.

This book is a revision of the various essays of the author, most of which have been published from time to time in this JOURNAL. His "theory" being: 1. Full acceptance of the microbic causation of typhoid fever; 2, an opinion that the bacilli in question may be destroyed in the body; 3, in consequence of that destruction the fever may be aborted or cut short. The means of accomplishing these laudible objects, Dr. Woodbridge thinks is found in the small doses of calomel and other drugs which he specifies. Few statements have met with more vituperative comment than the statement that typhoid fever may be cut short or aborted, and Dr. Woodbridge is not to be blamed if he repels some of the attacks with some heat, although enthusiastic as he is, he must admit that the majority is against his doctrine to-day. Whatever may be urged against Dr. Woodbridge's theories of treatment, all can agree with his notions of prophylaxis, which consist in the application of all known means of securing a good supply of pure drinking water and of preserving that water supply from pollution.

The chapter on diagnosis is an excellent one, and the book as a whole will constitute a valuable addition to the literature of the subject.

Instead of a series of essays, we look to see the work at its next edition grow into a systematic monograph on typhoid fever, for whether the antiseptic treatment of typhoid shall be generally adopted or not, the discussion on symptomatology, etiology and diagnosis will always be of value. The controversial character of the first essays in the volume are bound to attract attention, but in the next edition we trust the author may find it expedient to eliminate all that part of the book.

The Diagnosis and Treatment of the Diseases of the Rectum, Being a Practical Treatise on Fistula, Piles, Fissure and Painful Ulcer, Proctidientia, Polypus, Stricture, Cancer, etc. By WILLIAM ALLINGHAM, F.R.C.S., Eng., and HERBERT W. ALLINGHAM, F.R.C.S., Eng. Sixth edition. Cl., 8vo, pp. 485. New York: William Wood & Co. 1896.

When a book has reached its sixth edition it has passed beyond ordinary criticism. We can only note changes, and satisfy ourselves by reference that recent literature has been

considered. In this respect the sixth edition of Allingham is not disappointing. In the treatment of internal hemorrhoids the Messrs. Allingham still prefer the ligature as a rule. They however give a careful review of other methods. In regard to injection by carbolic acid and other substances, they quote with approval. Matthews and Andrews, and say: "For our own part we agree with Dr. Matthews. We have tried the injection plan in many cases, but there was generally much pain, more inflammation than was desirable, a lengthy treatment and the result doubtful—certainly not a radical cure. For it must be borne in mind that though the injection of carbolic acid into the interior of piles may in some instances stop the bleeding for a time, yet it can not and does not in any way remove the tumors." Beside this, the danger of embolism is pointed out. We think the authors do not do full justice to the "clamp and cautery" operation, which is not only dismissed with scant reference, but with condemnation. "This operation has little to recommend it. As regards danger to life—after all, the issue of greatest moment—as far as our most careful researches have led to a conclusion, it is quite six times as fatal as the ligature properly and dexterously applied." In the Rush Medical College clinic, Chicago, both operators use the clamp with cautery, and in five years no case of severe hemorrhage has been recorded, but the clamp used is of the Smith pattern, quite different from the Allingham clamp, and for the prevention of after-hemorrhage the hard rectal tube covered with iodoform gauze is used. The pressure exerted by this tube is an entire support to the eschar formed by the red-hot iron. The authors favor colotomy in selected cases, but the operation should be either inguinal or lumbar as the nature of the case indicates. No surgeon's library may be considered complete without this edition of this old favorite.

Jahrbuch der Practischen Medicin. (Yearbook of Practical Medicine. By Dr. J. SCHWALBE. Stuttgart: Ferdinand Enke. 1896.

This annual publication has been for many years a convenient and fruitful source of information to the German medical profession. To the English and American physicians the title of the work is misleading, as the book contains not only an accurate account of what has been done in the practice of medicine during the last year, but is equally reliable in giving valuable information of the advances in surgery, gynecology, obstetrics, ophthalmology, sanitation, physiology, pharmacy, etc., during the same period of time. Dr. Schwalbe has the assistance of a large corps of collaborators, and each one appears to have done his work well. The marginal annotations of the names of authors and subject matter are an important and convenient feature of the book. The work is not as exhaustive as Virchow's *Jahrsbericht*, but equally valuable and much more convenient for the busy general practitioner. It is an exceedingly useful work for reference, which should be in the hands of every German speaking physician and surgeon.

The National Formulary of Unofficial Preparations. Revised edition. By authority of the American Pharmaceutical Association. Cl., 8vo, pp. 195. 1896.

This is the second revision of this well-known work. The revision committee was composed of the following well-known members of the American Pharmaceutical Association: C. Lewis Diehl, A. B. Stevens, C. T. P. Fennel and Chas. Caspari, Jr. Most of the articles, or at least a large portion of them, should have been included in the U. S. Pharmacopeia, but even then we suppose as some sort of a supplement to the Pharmacopeia. In this edition the formulas of such preparations as were dropped from the last Pharmacopeia have been included. The decimal system of weights and measures has been introduced, and the work is now, in the language of the committee, "abreast of the times." We commend it to the profession.

Transactions of the Royal Academy of Medicine in Ireland. Vol. XIII. Edited by WILLIAM THOMSON, M.A., F.R.C.S., General Secretary; surgeon to the Richmond Hospital, Dublin. Cl., 8vo. Dublin: Fannin & Co., Ltd. 1895.

In this volume the high standard of its predecessors has been maintained. It is divided into six sections as follow: Medicine, surgery, obstetrics, pathology, state medicine, anatomy and physiology, containing articles by some of the most eminent of the European medical men.

Archives of Clinical Skiagraphy. By SYDNEY ROWLAND, B.A. Camb. The first number has just been published. Price, 4s. net per issue; with postage, 4s. 4½d. London: The Rebman Publishing Company, Limited.

This will be a record of the progress of medical photography and its various branches. Each number will contain six handsome collotypes, printed on the finest art paper and representing clinical cases in which diagnosis has been effected with the aid of Röntgen's X Rays. (The size of each plate is 10 by 12 inches.) Each plate is accompanied by explanatory text, printed on the best supercalendered paper (10 by 12 inches). The first number contains an introduction giving a full illustrated description of the methods relating to skiagraphy.

The Three Ethical Codes. Price, 50 cents. Detroit, Mich.: The Illustrated Medical Journal Co., Publishers.

This purports to give the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION, the American Institute of Homeopathy and the National Eclectic Medical Society. It is in convenient size and well printed.

The Audiphone and How to Use It in Hearing Through the Teeth. By RICHARD S. RHODES. Cl., 8vo, pp. 35. Chicago: Rhodes & McClure. 1895.

This book comprises a lecture on the audiphone and its use in hearing through the teeth, delivered by its inventor, Dr. Rhodes, before the fourteenth convention of American teachers of the deaf, at Flint, Mich.

NECROLOGY.

AGATHON WERNICH, at Berlin, aged 53. His name is familiar to Americans by his studies on abdominal typhus, beri-beri, etc., and his numerous contributions to hygiene and medical jurisprudence. He was, perhaps, better known at the antipodes, as he was for three years professor at the College of Physicians and Surgeons of Tokio when it was first opened. As a practical and scientific physician his loss is sadly felt in Berlin.

GERMAIN SÉE. Paris paid the last honors, May 17, to this distinguished physician, "the apostle of physiologic therapeutics." Although he did not add anything directly to the "materia medica," yet many of our most important remedies owe their prompt appreciation and adoption to his broad and constant outlook over the international world of science, and his ability to perceive and decide what was of true value in the new things presented. He stood sponsor in this way for the salicylates in the treatment of rheumatism, for potassium iodid in asthma, for caffeine and theobromin in renal and cardiac insufficiency, etc. His articles on the treatment of typhoid fever with quinin and alcohol, on strophanthin, terpin, etc., are classics, while those who have been signaling albuminuria as the result of antitoxin treatment of diphtheria, should read Sée's article on "Croupous Albuminuria" published in 1858. His large works, "Médecine Clinique," "Exper. Pathology," etc., are too well known to need mention.

DAVID C. CHAMBERLAIN, M.D. (Castleton Medical College, Castleton, Vt., 1837), of Leroy, N. Y., at Detroit, Mich., June 4, aged 81. He was a surgeon of volunteers during the late war.—ANA HOW, M.D. (Western Reserve University Medical Department, 1886), at Fairfield, Iowa, June 5, aged 78. He founded the Iowa Institution of Science.—J. W. PHIPPS,

M.D. (Rush Medical College, 1850), at Evansville, Ind., June 8, aged 79. He was a veteran of the late civil war, having served as a surgeon in the Eighth Illinois Volunteers.—B. G. CULVER, M.D., at Kane, Mo., May 28, aged 65.—M. H. PICOT, M.D. (Jefferson Medical College, 1861), at Geneva, N. Y., June 5.—JOHN GILLESPIE, M.D. (Harvard University Medical School, Boston, Mass., 1885), at Boston, Mass., June 5, aged 36.—JOHN MCLEAN FLEMMING, M.D. (Rush Medical College, 1872), at Chicago, Ill., June 10, aged 50.—EDWIN A. HILL, M.D. (Harvard University Medical School, Boston, Mass., 1850), at East Killingly, Conn., of hepatic cancer, May 30.—DR. O. T. AZBILL, M.D., died suddenly on June 7 at his home near Big Hill, Ky., of apoplexy. He was about 60 years old.

MISCELLANY.

Franklin E. Murphy, M.D., has been elected secretary of the Kansas City Medical College.

Arthur R. Elliott, M.D., of Chicago, has been elected Professor of Preventive Medicine and Urinary Diagnosis, at the Post-Graduate School, Chicago.

Health Office Report.—The health Office report at Detroit, Mich., for week ending June 6, 1896: Deaths: Under 5 years 35, total 85; births, male 52, female 40, total 92. Contagious diseases: diphtheria, last report 17, new cases 4, recovered 13, died 1; scarlet fever, last report 23, new cases 8, recovered 8; measles, last report 3, new cases 1, recovered 2.

Asked to Change its Name.—Press dispatches of June 13, state that President Eliot, of Harvard University, has filed a bill in the Federal court asking that the "Harvard" Medical College of Chicago take some other name. It is to be hoped that success will crown the efforts of the Massachusetts school, as it is too palpable an attempt to make capital out of a great name.

Woman's Medical College, Baltimore.—This college has lengthened its annual course to eight months (October 1 to June 2). The following appointments have been made in the faculty: R. Tunstall Taylor, M.D., Professor of Orthopedics; Thomas C. Gilchrist, M.R.C.S., Professor of Dermatology; Henry P. Hynson, Ph.G., Professor of Pharmacy; G. Milton Linthicum, M.D., Professor of Physiology; Kemp Battle Batchelor, M.D., Associate Professor of Obstetrics. A chair of Mental Diseases has been added; also department of bacteriology and embryology.

Menthol in Gastric Diseases.—Dr. A. L. Benedict, in the *American Therapist*, speaks favorably of menthol, as follows: It is an excellent antiseptic for stomach and intestine. I usually employ ten centigram doses, two or three hours after meals, to act in the intestine. For the stomach I prefer to spray it through the stomach tube. Aside from its antiseptic properties, this drug is stimulating to the local blood supply, and hence, to secretion, and it also relieves painful spasm of smooth muscle.

Must Receive all Insane.—A resolution was passed by the House of delegates of Virginia, in which the senate concurred, and which was approved March 4, 1896, that all persons who have been legally adjudged insane, who have or may hereafter make application for admission into a State hospital, shall be received. The superintendents of the several State hospitals shall be required to send promptly for all such insane persons and receive them until all vacancies in the same are filled.

Can Marry.—Sections 2224 and 2225 of the code of Virginia were amended by the 1895-6 general assembly so that the former section shall not be construed as prohibiting a man from marrying an aunt of his former wife, and the latter section no longer contains the provision that no woman shall marry the

husband of her brother's or sister's daughter, adding that if any woman shall have heretofore married her brother's or sister's deceased daughter's husband, such marriage shall be considered valid.

Can Have Order for Examination Modified.—The general term of the city court of New York holds, in the case of *Lawrence v. Samuels*, April 27, 1896, that, in a personal injury case, where the defendant procures an order from the court, that the plaintiff, a female, submit to an examination, before trial, by a physician named in the order, the fact that the order compels her to submit to an examination by a physician not of her own sex, is not a ground for the vacation of the order, she not having made any effort to have the order modified, though, as the New York code provides that she may require the examination to be made by such a physician, it furnishes ground for applying to have the order modified.

The Homeopathic Crusade.—Senator Gallinger's report in favor of legislation to restrict animal experimentation in the District of Columbia, which is a rehash of the report of the American Humane Association, brings to light the important fact that the homeopathic fraternity has originated and is pushing this crusade against scientific investigation and progress. It is a clandestine effort to humiliate the science of medicine. The Senator concludes his report with the statement that it is the unanimous expression of opinion by the Senate Committee on the District of Columbia, which is equivalent to the assertion that the Senate of the United States will unite with him in the promotion of this homeopathic crusade. Will the profession submit?

Case for Expert Testimony.—Whether criminal charges preferred by a female patient against a physician are the result of hallucination, while under the influence of chloroform and ether, the supreme court of appeals of West Virginia holds, in the case of *State v. Perry*, decided March 18, 1896, is a question that must be determined by expert medical evidence, as it is not a matter of ordinary human experience or knowledge. If such testimony establishes the probability of such hallucination, and such charges depend entirely on the uncorroborated and contradicted testimony of such patient, the jury, it says, should acquit the accused. Whether a person with a wooden leg is incapacitated from kneeling, and thereby rendered incapable of committing an offense while kneeling, in the manner charged in this case, the court also holds as a subject-matter of inquiry justifying the introduction of expert medical testimony, to assist the jury in arriving at a correct conclusion.

Hot Water Baths in Two Cases of Cerebro-spinal Meningitis.—Woroschilski has followed the example of Aufrecht and employed baths at 32 C. in a couple of cases of severe cerebro-spinal meningitis, with such success that he thinks this treatment should be widely adopted. The effect from the first bath was surprising. The irregular pulse became regular, the temperature fell, and the patient felt so much improved in every way that he begged for more. One case was complicated with heart disease, but the relief was equal to the other. The usual remedies, ice, calomel, iodine, etc., were also given. Bälz and Renaut have also advocated hot baths in children's bronchitis.—*Memorabilien*, April. This treatment has been used in America for a long time. In a local epidemic of 1873 in Illinois, there was much testimony in favor of the benefit of warm water immersion.

Treatment of Acne.—Franke states in the *Med. Neuigkeiten*, that the important point in treating acne is to prevent the transference of the infective germs to new localities and glands. Hence he strictly forbids all massage. Each papule must be allowed to develop naturally undisturbed. When it is ripe, the pus discharged on slight pressure should be carefully wiped off with a clean rag, and the skin around it disinfected with a 1 to 1,000 sublimate solution, concluding with the application

of a thin layer of ungt. len. The skin of the face must never be touched with the bare fingers, and they must not come in contact with the skin anywhere after handling the ripe papule. Excellent results, according to Franke, follow this treatment if persevered in for months.—*Memorabilien*, April.

Rush Medical College.—The annual commencement exercises of Rush Medical College, Chicago, were held May 27. The audience that assembled to witness the exercises was a large one. The degree of Doctor of Medicine was conferred upon 211 candidates. Beside the usual degrees, an honorary degree was conferred on Dr. Nathan M. Dobson of Berlin, Wis. Prof. H. M. Lyman delivered the doctorate address. Sumner A. Edmunds was valedictorian. The faculty and members of the Alumni Association held the annual banquet of the college at the Auditorium Hotel. Nearly six hundred guests were present and the occasion was made most enjoyable. Dr. A. C. Cotton, a graduate in the class of 1878, officiated. Among the speakers were President William R. Harper of Chicago University, Luther Latlin Mills, Dr. J. B. Hamilton and Dr. J. E. Cox.

"Palatable Castor Oil."—We are in receipt of the following letter from Mr. A. J. White, of New York, in which he encloses a list of patents dating from Sept. 10, 1889, to Aug. 14, 1894, inclusive, and warning druggists against using this formula, because of liability to lawsuits for infringement of patent. We have no personal knowledge of the case. We quote Mr. White's letter for general information.

NEW YORK, June 6, 1896.

To the Editor:—A paragraph is going the rounds of the medical journals, giving a formula for making Palatable Castor Oil. This formula is patented as per following list of patents:

No. 410,940, dated Sept. 10, 1889; No. 470,715, dated March 15, 1892; No. 470,714, dated March 15, 1892; No. 524,513, dated Aug. 14, 1894; No. 524,514, dated Aug. 14, 1894; and if druggists are induced to prepare this article themselves, it will lead to a multitude of lawsuits like those instituted in the "Drive Well" case. Some scheming lawyer would like to take up this case for one-half the profits, and I think the journals should warn the druggists so that they may not be caught in a trap. Yours very truly, A. J. WHITE.

Professor Edwin Klebs. The removal of Professor Klebs to Chicago has been signalized by his immediate appointment as Professor of Pathology in Rush Medical College and in the Post-Graduate Medical School. This distinguished bacteriologist is already well known in America, but as a reminder to our readers of the valuable services of Professor Klebs, we append a list of the titles of some of his more important papers. His appearance is that of a well preserved, good humored, scientific gentleman, without a tinge of brusqueness or hauteur, still in vigorous manhood.

America, and particularly Chicago, should be congratulated on this notable acquisition to the teaching force of the Northwestern metropolis.

KLEBS, EDWIN: *Handbuch der Pathologischen Anatomie*. Berlin. A. Hirschwald, 1868 80.

Beiträge zur Pathologischen Anatomie der Schusswunden. Nach Beobachtungen in den Kriegslazarethen in Carlsruhe, 1870-1871. Leipzig, 1872.

Studien über die Verbreitung des Cretinismus in Oesterreich sowie über die Ursache der Kropfbildung. Prag, 1877.

Ueber die Umgestaltung der Medicinischen Anschauungen in den letzten drei Jahrzehnten, Vortrag. Nebst einem Vorwort enthaltend die Entgegnung auf Virchow's Rede über Die Freiheit der Wissenschaft im Modern Staat. Leipzig, 1878.

Ueber Cellularpathologie und Infectiouskrankheiten. Prag, 1878.

Ueber Cholera Asiatica. Nach Beobachtungen in Genua. Basel, 1885.

Die Trinkwasserversorgung der Stadt Zürich und ihrer Ausgemeinden. 1885.

Die Causale Behandlung der Tuberculose. Pp. 500: Leipzig, 1894.

Klebs was also editor of the *Correspondenz-Blatt für*

Schweitzer Aerzte, in 1871. His work in the Berne Pathologic Institute (Würzburg, 1873) and with Tommasi-Crudelli on Malaria are of international interest.

His great work on General Pathologie, Jena, 1886, is, however, that on which his fame will chiefly rest. The fact remains, however, that at this time Professor Klebs, in Pathology, is second only to Virchow.

Practical Notes.

Advantage of Using Warm Solutions of Cocain.—Costa has found that the local anesthetic effect obtained with cocain is more rapid, more intense and more lasting, if the solution is warm. The dangers of intoxication are thus much diminished, as the quantity of cocain can be very much reduced, if it is warmed. A solution at 0.5 or 0.4 per cent. heated, will produce a powerful effect.—*Semaine Médicale*, May 9.

Nicotin Soap in Dermatology.—The use of soap strongly impregnated with nicotin is recommended in the *Monatsh. f. prak. Derm.* Vol. xxi, No. 12, for cutaneous diseases produced by a parasite, especially for scabies. It is effective, cheap and easily used by anyone, although it should be watched to prevent accidents from its use, as it has been known to produce vomiting in a child, with change in the pulse. The soap should contain about 0.7 per cent. nicotin, or extract of tobacco.—*Nouveaux Remèdes*, May 24.

An Excellent Diagnosis by the Roentgen Rays.—We have a photograph giving not only a clear illustration of the Roentgen process but a clear diagnosis in a case which could not otherwise be made out. Dr. Charles Denison, who sends it to us, says that several physicians saw the arm, but all were uncertain as to what had occurred. The old lady, in falling to the ground, had received the force of the fall upon the palm of the hand and had sought no physician's advice till nearly four weeks after the injury. The impaction of the shaft of the radius into the head of the bone is very clearly shown. The work was done by the Mountain Electric Company in Denver, under the supervision of Mr. Charles F. Lacombe.

Treatment of Alopecia Areata with Acetic Acid and Scarifications.—Faivre ascribes this affection to a micrococcus (Vaillard's), and has found that by slightly scarifying the surface with the point of a bistoury and painting it with acetic acid, a growth of pathogenic staphylococci substitutes the former growth, and recovery ensues. After the slight eschar thus produced has fallen off, a growth of natural hair follows, unless the trouble is complicated with a destructive folliculitis, or it proves to be the decalvant form, which resists all treatment and is probably of tropho-neurotic origin. It may be necessary to repeat the operation every day for a month, or more. Rigorous antiseptic precautions should be taken to prepare for the scarifications, and to prevent the spread of the affection in all its stages. Full details of this treatment are given with reports of cases in the *Archives Cliniques de Bordeaux* for April.

Washington.

WEEKLY REPORT OF HEALTH OFFICE.—The report of the Health Officer for the week ending June 6, 1896, is as follows: As reported the deaths numbered 83, while for the previous week they amounted to 85. The death rate for the week was 15.63 for the total inhabitants, that for the whites being 13.58, and that for the colored 20.11. The annual average death rate for the District of Columbia is 23.67, being 18.84 for the whites and 33.44 for the colored. Of diphtheria 3 new cases and 1 death were reported. No house was released from quarantine and six remained placarded. No death from scarlet fever occurred; 3 new cases were reported; three premises relieved from quarantine, leaving eight in quarantine.

IMPOSTOR FOOLS THE DOCTORS.—An alleged deaf and dumb man has been securing donations from medical men in this city by presenting a certificate of disability purporting to be signed by Dr. G. W. Cook. Quite a number were victimized.

VACCINATION WILL NOT BE PAID FOR.—A great injustice has been done to the Physicians to the Poor of this city by Congress striking out the item in the Appropriation bill of \$1,500 to pay those physicians for extra work in vaccinating a large number of persons during the smallpox epidemic last year.

THE BOARD OF MEDICAL EXAMINERS for the District of Columbia will in a short time be appointed by the Commissioners as provided for in the new law regulating the practice of medicine and surgery in the District. They have sent notices to the medical societies of the city, from whose members the examiners will be selected. The societies are requested in these notices to furnish the names of their members within fifteen days. According to the act, the Commissioners are to appoint three boards of medical examiners, one for each school of medicine. The passage of this bill has been desired for the past twenty years and is now a law. The credit of its passage is due almost entirely to the personal efforts of Dr. Samuel C. Busey, President of the Medical Society and chairman of the legislation committee, who has given most of his time in looking after medical bills of benefit and interest to the medical profession. This JOURNAL has added its influence in these matters.

APPOINTED PROFESSOR IN HOWARD UNIVERSITY.—At the last meeting of the faculty of Howard University Dr. Charles Emmons was elected professor of mental diseases.

FOR THE HOME FOR INCURABLES.—A little over a year ago a chain letter scheme was started for the benefit of the Home for Incurables. It has met with a generous response, and has brought in \$1,735.

A NEW HOME AND HOSPITAL.—Articles incorporating "The National Hospital and Orphanage" have been filed by Rachel E. Tomlinson, president; Amelia Marggraf, vice-president; Edith A. Bauer, secretary; Sarah J. Douglas, financial secretary; Eliza A. B. Chambers, treasurer. The purposes of the association are to provide a home and care for homeless, aged and indigent men and women, and also a hospital, as well as to educate, care and provide for orphans and homeless children without regard to sect or creed.

ITEMS INCLUDED IN THE DISTRICT APPROPRIATIONS BILL.—Under the health department the following organization is authorized: Health officer, \$2,000; nine inspectors at \$1,200; sanitary inspector, who shall also be a chemist, \$1,500; inspector of live stock and dairy farms, \$1,200; inspector of marine products, \$1,200; chief clerk, \$1,800; clerk, \$1,400; four clerks at \$1,200, two of whom may also act as inspectors; clerk, \$1,000; janitor, \$600; poundmaster, \$1,200; laborers, 1,920; driver, \$480; in all, \$30,000. Other items under the health department are: Rent of stable, \$120; collection of garbage, dead animals and the distribution, \$57,000; enforcement of the act to prevent the spread of scarlet fever and diphtheria, \$5,030; for ambulance for contagious diseases, \$350; for the relief of poor, \$13,000; Central Dispensary and Emergency Hospital, \$15,000; Children's Hospital \$10,000; Homeopathic Hospital, \$8,500; Washington Hospital for Foundlings, \$1,000; Eastern Dispensary, \$1,000; Home for Incurables, \$1,000; Columbia Hospital for Women, \$25,000, including pairs.

FREEDMEN'S HOSPITAL AND ASYLUM.—For subsistence, 2,500; for salaries, \$16,000; for rent of hospital buildings and grounds, \$4,000; for miscellaneous expenses, \$11,500.

The following important proviso was added: Provided, that no member or members of any board or boards of trustees or directors of any charitable institution, organization or corporation in the District of Columbia, which is supported in whole or in part by appropriations made by Congress, shall engage in traffic with said institution, organization or corporation for pecuniary gain, and any member or members of such board of trustees or directors who shall so engage in such traffic shall be deemed now and hereafter legally disqualified for service on said board or boards.

SUICIDE IN ST. ELIZABETH'S ASYLUM.—An insane inmate of St. Elizabeth's Hospital committed suicide on the 11th inst., by hanging himself to the iron bars of his cell. He was discovered dead the following morning.

Philadelphia.

THE FIRST EXAMINATION IN OPHTHALMOLOGY AT THE JEFFERSON.—In connection with the very interesting series of papers recently read before the Academy of Medicine, discussing the best methods of teaching various branches of medical study, it may be of some interest to refer to the results of the examinations upon ophthalmology of the last graduating class of Jefferson Medical College. It may be said in explanation that two circumstances make this examination a memorable one: One being that this is the first time in the history of the college when this examination was made obligatory and its results taken into consideration in determining the standing of the candidate for the degree; the other being that the next course will inaugurate a radical change in the system of teaching ophthalmology at this school. In the four-year graded course, the members of the graduating class only, will be required to attend one lecture per week, and class sections will attend daily clinical demonstration and the quizzes, under the direction of Professor William Thomson, Clinical Professors Howard F. Hansell and G. E. DeSchweinitz, and their Chief Assistants, Drs. Sweet and Veasey. The class that had just graduated has had the opportunity of attending weekly lectures upon ophthalmology during the last three years, and also the daily clinics which were established twenty-four years ago by Professor Thomson, and have formed an integral and important part of the teaching at this school since that time. The results of the examination may be summarized as follows: The number examined was 229; of whom twelve received the highest mark 100; from 90 to 99 was taken by ninety-nine; from 70 to 89 by ninety; from 60 to 70 by fifteen; and below the minimum of 60 was received by only thirteen. It is seen that over 200 passed above 70 and that nearly half passed above 90, only twenty-eight were below 70, which might well have been taken as the minimum. Those who passed high had attended the clinics regularly and were members of the quiz classes; those who fell below the average had evidently made little or no use of their advantages. A gold medal for an essay on Color Blindness was awarded at the Commencement to Albert W. Garren, Jr., of Philadelphia. It may be of interest to teachers of this branch to publish the list of questions asked at the first examination upon ophthalmology at the Jefferson Medical College. On account of the size of the class it was divided and examined on two successive afternoons. The examinations were in writing and the time was not limited.

QUESTIONS: What is meant by normal acuteness of vision; and how is it tested and expressed? 2. What are the most common constitutional conditions that may be revealed by an ophthalmoscopic examination? 3. Give a brief definition of the chief anomalies of refraction. 4. How may a concomitant squint be distinguished from a paralytic squint? 5. What are the prophylaxis and treatment of ophthalmia neonatorum? 6. What should be done to check the progress of a corneal ulcer? 7. How would you distinguish between acute iritis and acute glaucoma? 8. What are the causes, symptoms and treatment of interstitial keratitis? 9. Describe the methods for the diagnosis and treatment of cataract. 10. What is meant by the "dangerous zone" of the eye, and what are the dangers of injuries in that region?

(Second set.) 1. Give the differential diagnosis of iritis and conjunctivitis. 2. What is the proper treatment, local and constitutional, of acute syphilitic iritis? 3. Describe the operations of enucleation of the eyeball. 4. What operations are used in the treatment of congenital and senile cataract? 5. What is epiphora and its treatment? 6. What is central scotoma and give its causes? 7. What are the errors of refraction and how are they corrected? 8. What reflex symptoms attend ametropia? 9. What relation is there between internal squint and hypermetropia? 10. What is the treatment of internal squint combined with hypermetropia?

Louisville.

THE HOSPITAL COLLEGE OF MEDICINE, of Louisville, has purchased a lot adjoining the college buildings for the erection of a hospital. Ground will be broken immediately and the work will be pushed to completion before the opening of the session of 1897. The hospital will have a modern clinical and operating theater with seating capacity for 300 students, with ample wards and private rooms, and will be a most important addition to the teaching facilities of the college.

THE KENTUCKY SCHOOL OF MEDICINE held its annual commencement on June 16. The Hospital College of Medicine held its graduating exercises on the 18th.

JENNIE CASSEDAY INFIRMARY.—Two graduates of the training school for nurses of this institution were awarded diplomas at the completion of their course on the 8th inst. The address was made by Dr. J. M. Mathews and by the Rev. Mr. Jennings, at the conclusion of which the assembled guests were shown through the infirmary and a collation was served.

LOUISVILLE COLLEGE OF MEDICINE.—At the faculty meeting recently held the announcements of the changes in the personnel of the faculty was made. As already announced in these columns, Dr. A. M. Cartledge was elected to succeed Dr. J. A. Ireland, who was made emeritus Professor of Gynecology; Dr. W. C. Dugan was made Professor of Surgery in the place of Dr. Cartledge; Dr. J. W. Guest will be Clinical Assistant to the Chair of Surgery; Dr. J. W. Williams will be Lecturer on Proctology; and Dr. Curran Pope will lecture upon Diseases of the Mind and Nervous System. This leaves a vacancy in the Assistant Staff of the Kentucky School, Dr. Guest resigning as Assistant in Gynecology and Abdominal Surgery, and Dr. Pope resigns from the Hospital College of Medicine where he held the same position as the one in the Louisville School. Dr. Harris Kelly has been made Lecturer on Histology and Chemistry.

FEEBLE-MINDED INSTITUTE.—Dr. J. P. Huff, the Superintendent of the Institution for Feeble-Minded Children located in Frankfort, received the World's Fair medal and certificate of first award granted to Kentucky for the finest and best display of work done by any institution for feeble-minded children. The medal is a handsome bronze affair and the certificate of award is engraved on parchment.

TEMPERATURE.—A case of malaria developed in the person of one of the children of the Masonic Widows' and Orphans' Home, aged about 11 years, in which the temperature reached 107.5 degrees. This was tested by several thermometers, two of them being registered Hicks.

DURING THE EXAMINATION of students for degrees at the Hospital College of Medicine a bottle of bromin exploded in the hands of Prof. Philip F. Barbour, by which he was badly burned, and a student was also seriously burned, also inhaling some of the fumes from which a bronchitis has developed and he is in a serious condition. Dr. Barbour's injuries were only burns on the hands and wrist but were very painful.

STATE BOARD OF HEALTH.—The regular meeting of this board was held June 9. Dr. Mathews was re-elected president; Dr. McCormack, secretary; Dr. Eisenman, veterinary surgeon; Jno. L. Long, sanitary inspector; Jno. Cashin, bacteriologist. Drs. Kinnard and Samuels are the new members appointed in the place of Drs. Beeler and Lucy, whose terms had expired. Dr. Long submitted a report of his investigations of epidemics of smallpox through the State. Representatives of the Physio-Medical College of Indianapolis appeared before the board requesting that their diplomas be recognized by the board, but on consideration the board refused to grant their request. Dr. McReynolds offered the following resolution, which was adopted: "Resolved that the State Board of Health requests the State Medical Society to recommend the passage of a statute by the next Legislature to punish the crime of abortion. That the Society be requested to instruct the president to appoint a committee of five to investigate the laws and urge the passage of a law by the legislature." Dr. McReynolds, speaking to the above, cited the case of a man in Owen County who was fined \$300 in the lower court, but this decision was reversed in the court of appeals, Judge Hines in handing down his decision stated that there should be a law to cover this crime. The following resolution was also passed by the board: "Resolved that the State Board of Health of Kentucky regards the intentional production of abortion upon any woman either before or after quickening (unless it shall be deemed necessary after consultation with at least one licensed physician of good moral character to preserve the life of the woman). The State Board of Health will revoke the license of any physician found guilty of such crime. An attempt to conceal the fact that an abortion was produced will be considered as *prima facie* evidence that it was not done to preserve the life of the woman." The committee appointed to consider the President's address reported as follows: "We heartily endorse the paper so ably prepared and delivered to-day, which we recommend for adoption and publication that the profession may be benefited thereby. We suggest that the State Board of Health take immediate steps to abate the spitting nuisance and if possible interest the State and municipal

authorities in the suppression of this evil. We would dissent from the New York requirements for graduation, in that we hold that a college education is not a requisite, but that a good, thorough education in English in some academy or high school is sufficient preliminary training for the majority. It is not our intention to discourage a thorough literary course for medical students, but such an education is impossible to many worthy young men who wish to enter upon the study of medicine. We would not have the board discriminate against the diplomas from medical colleges in small cities, for many of them are controlled by men eminent in our profession and their graduates are the peers of educated men from the colleges in the larger cities. The address of President Mathews should be widely read and the principles enunciated carried into practice."

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from June 6 to June 12, 1896.

Capt. Philip G. Wales, Asst. Surgeon, is relieved from temporary duty at Ft. Monroe, Va., and will return to his proper station, Ft. McPherson, Ga.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending June 13, 1896.

P. A. Surgeon P. H. Bryant, ordered to naval station, Newport, R. I. Asst. Surgeon C. M. De Valin, detached from the Chelsea (Mass.) hospital, and ordered to the "Blake."

P. A. Surgeon E. R. Stitt, detached from the "Bache" and ordered to the "Vermont" June 15.

Change of Address.

Baird, T. M., from Forest City, Ark., to Thurber, Texas.
Bartlett, R. H., from 167 Dearborn St. to 125 La Salle St., Chicago, Ill.
Beegle, H. B., from Chicago to Blue Island, Ill.
Brauns, E., from 3 Lincoln Av. to 510 Cleveland Av., Chicago, Ill.
Caldwell, Joseph R., from New Hamburg to Greenville, Pa.

PRECEDENT CAUSES OF TUBERCULOSIS.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY J. WELLINGTON BYERS, M.D.

CHARLOTTE, N. C.

I invite your attention to some views in regard to the condition that has been designated as the precedent or pretubercular stage of consumption. That there is such a condition capable of distinct clinical position and recognition, is very generally conceded, though as to the exact nature of its underlying phenomena there remains much yet to be determined. We are not, however, without some useful and guiding data and such as we do possess has not received the consideration that the condition would appear to warrant.

We have reached a position where we can appreciate the discoveries and bearing of the work of Koch, and we realize the fact that these have not furnished the therapeutic resources that their first announcement seemed to promise. Influenced by this fact, investigation has been compelled to turn to other paths of work. The history of the pathology of tuberculosis has been varied. Our earliest conceptions of the disease was that it was pus, a process of suppuration; second, that it was inflammatory nodules; third, that these were distinct tubercles; fourth, that these tubercles contained a virus; fifth, that this virus was inoculable; sixth, that inoculability was due to a specific bacillus. When this sixth and last stage of our knowledge was reached a strong hope possessed us that means for the prevention and cure of tuberculosis would soon be forthcoming. So far this has been a series of disappointments and we do not possess a single remedy capable of effecting anything like a cure of this disease. Baffled by repeated efforts to treat tuberculosis from its bacteriologic standpoint, research has turned to an investigation of its precedent causes, and is making an effort to detect and control those contributing factors, as the only possible means of modifying this disorder. Clinical experience has long taught that pulmonary tuberculosis to be successfully combatted must be taken in its very earliest stage and that the ratio of arrests, or cures, is invariably in proportion to the recency of the disease. The reason for this is now plain. The older theories of Virchow which showed that the disposition to tuberculosis was the same as the disposition to inflammation and that the primary foci constituting the anatomical basis for the implantation of the bacilli and the production of tuberculosis, was a previous inflammation, and now admitted as the correct ones. It has been established that tubercular changes are always secondary to inflammation and that infection of the human organism does not occur in the

absence of the latter. These precedent causes, consisting of changes in the integrity of the tissues and cells, are local and general, acquired and hereditary. Before the bacilli can enter and flourish there must exist certain favorable conditions in the soil. The fact that it is not always possible to point out the precise location or seat of these vulnerable foci in no way invalidates the correctness of this statement; they must always be present. Experiment, experience and analogy all demonstrate that tuberculosis is never primary but secondary in time and pathologic importance. In the normal condition of the tissues no foci exist and the bacilli entering through the respiratory channels are removed with the expectoration or destroyed by the phagocytes. The system is in this way kept immune. If, however, the pulmonary tissue contain lesions, or foci, the effect of previous inflammatory disease, such as tracheitis, bronchitis or broncho-pneumonia, or foci such as are produced by foreign bodies incident to the occupations of stonecutters, cutlery works and the like, they constitute vulnerable points for the implantation of the bacilli, and are liable to invite tuberculosis. It is almost certain that the presence or absence of these points in the lungs constitute the real basis for the difference of susceptibility manifested at different periods. Croupous pneumonia is rarely followed by tuberculosis, though furnishing the gravest changes in the lungs. The reason for this is that the exudation in the alveoli consists largely of fibrin and leucocytes, which quickly break down and is soon reabsorbed, and the bacilli find no foci to infect. In bronchitis and catarrhal pneumonia the absorption is much slower, the products of inflammation last longer and the bacilli have the favorable conditions present for a longer time and hence we find tuberculosis a frequent result. It is reasonable to conclude that these products of inflammation must constitute the controlling factors and operate in the manner stated. Niemeyer taught that tubercular changes were always originated in previous inflammatory conditions, and while he did not clearly interpret the meaning of them, he chronicled the fact which we are now able to understand. His views were abandoned only for a time, and we are again realizing their importance and truth. So far, tubercular processes are seen to be the result of inflammatory changes. There are, however, cases of tuberculosis in which no such factors form a part of their clinical history. The disease appears in the absence of bronchitis, broncho-pneumonia, whooping-cough, measles and other diseases involving the air passages, and also results from fevers, anemia, gastric and other diseases. How can the theory of primary inflammatory foci in the pulmonary tissues be made to fit these cases? In my opinion we must assume that the organism under certain conditions of nutrition, such as follow the diseases enumerated,

manufactures or produces defective blood cells or leucocytes. These leucocytes, following the general law of physiology, are either encysted or destroyed by the organism. When from any cause the blood-forming organs produce defective cells they are treated like other extraneous or foreign substances and destroyed, encapsulated or extruded. In the diseases mentioned this is, in all probability, the case: the imperfect leucocytes are extruded into the tissues and at different localities, such as the lungs, form nodules of dying or dead cells. These nodules set up a low grade of inflammatory reaction which may continue until infected by the bacilli or cast off by expectoration or destroyed by the phagocytes. Under these conditions the foci are present and constitute the same kind of pathologic seats as those following inflammatory diseases. That this is a correct view of the infecting process in tuberculosis, can be experimentally shown by the introduction of such substances into the tissues as bits of sponge, cork or cloth and allowing them to remain for a time. After awhile they are seen to induce inflammatory reaction of a very low grade, and later on become tubercular. The natural history of the bacilli shows that they never possess the power of unconditionally attacking the organism; that they are peculiar in their methods of invasion and invariably demand precedent conditions, causes or susceptibility in order to attack. Seeing the nature of these conditions, their place in the pathologic condition involved and their connection with the etiology of this disease the question may be asked here, can they be controlled? In the beginning, when the foci are few and small, we may hope to accomplish much by proper treatment. Loss of weight and capricious appetite are the first indications of altered nutrition. We should endeavor to meet these with proper food, exercise in the open air and other well recognized means. The possibilities of cure in this stage are numerous since the organism has not the toxic phenomena as a result of the pus cocci to contend with, which appears later on. We should direct our efforts toward removing the inflammatory nodules through tissue nutrition, thereby stimulating the processes of phagocytosis, absorption or fibrosis in the affected regions. In case we do not get the desired results the administration of an arsenic preparation to promote fatty metamorphosis and the hypophosphites to remove them might offer some advantage. The patient undergoing this treatment should be placed, as far as possible, in aseptic surroundings, such as mountains, in rural localities where the chances of bacillary infection are reduced to a minimum. The important point is to prevent the simple inflammatory process from becoming complicated by specific infection when it rapidly passes beyond ordinary measures of control. In subjects presenting evidence of hereditary influences we know that the bacilli are likely to thrive and we must not wait, but treat long before hemoptysis, pain in the side, wasting signs of active symptoms have appeared. We are too much inclined to give conservative advice in these cases and find later on that we should have been active in the work of prevention.

In this paper I have attempted to point out that the control of tuberculosis lies largely in its early and preventive stages. That its precedent causes, in inflammatory foci, are the result of previous disease. That the early recognition and treatment of this condition would remove the chief cause of tuberculosis.

SOME REMARKS ON THE MANAGEMENT OF VALVULAR CARDIAC DISEASE.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY GEORGE L. COLE, M.D.

LOS ANGELES, CAL.

I shall not consume the time of this society by entering into the history, etiology, etc., of valvular heart disease, but I do wish to say, by way of preface, a few words about prophylaxis. I had the pleasure of listening to the last course of lectures delivered by the late Austin Flint, in Bellevue Hospital Medical College, in the winter of 1885-6, and if there was any one fact that he endeavored to impress upon his class more than another, it was the duty of the physician, in treating articular rheumatism, to so adjust the treatment as to place the complication of valvular disease at the minimum. The question asked most frequently by him in the weekly "quiz" was, "What shall we do in acute articular rheumatism to render the patient least liable to cardiac complications?" The reply he wished was this: "Render the secretions of the body alkaline as speedily as possible, and in so doing not rely upon the salicylates alone." In other words, from the rich storehouse of knowledge garnered by over fifty years of conscientious, indefatigable and brilliant labor, came this *gem* to be handed down to posterity with emphasis, *i.e.*, that the stronger alkalies, such as sodium bicarbonate in large doses, are as essential, and even more so, early in the treatment, than the salicylates. When we remember the large percentage of valvular disease caused by articular rheumatism, it is easy to understand why this great master wished to so impress this truth upon his class that they should never forget its importance.

Regarding the management of the disease, it is to be remembered that there are other things to be taken into account than the medicinal treatment. Diet and regimen are two factors never to be neglected. The food should consist largely of nitrogenized material, taken in quantities that can be easily cared for by the stomach and digestive apparatus, and at intervals best adapted to the accomplishment of perfect assimilation. The secretions of the body are to be kept in as nearly a perfect a condition as possible. The emotions and passions are to be under the control of the patient, and he is to remember that upon such judicious control depends to no small degree the conserving of compensatory force. With regard to the question of enforced exercise as opposed to rest, I favor rest. Why there should have arisen an advocacy of mountain climbing, etc., in this condition, I am totally unable to comprehend any more than I can understand why a crippled dray horse should have his load increased instead of lightened in order to prolong his days of usefulness. Here I wish to be distinctly understood as referring to enforced exercise with the object of increasing the heart force. If by increased labor you wish to aid in elimination of urates and other poisonous material from the blood, or to reduce a flabby, obese structure in order to lessen the amount of labor required by the heart to sustain the circulation, I will agree that in a few well-selected cases there may be something to be gained, but such cases are extremely rare with us, and in the great majority of cases rest, both mental and physical, is absolutely necessary to the best interest of the patient.

In some cases of beginning loss of compensatory

force, prolonged rest in bed, by lessening the amount of work required of the heart, will restore compensation without any medicinal treatment. In all cases when possible, at such times, complete rest in the recumbent position for a time will do much to facilitate restoration.

With regard to the medicinal treatment, let me first say a few words about the most commonly used drug, digitalis. That many cases of valvular disease are treated with digitalis when it would be far better to use *no* remedy, is a truth which we should all bear in mind. The one great question in giving cardiac tonics is, "Has compensatory hypertrophy failed to make the power of the lame heart equal to the amount of work to be accomplished by it?" No matter how loud the murmur, no matter where the apex may be, no matter how large the superficial cardiac space; so long as hypertrophy is compensating for the valvular leakage or stenosis, so long should we religiously let cardiac tonics alone. But sooner or later there comes a time when hypertrophy ceases to compensate; there may be dyspnea, pulmonary congestion or edema, edema of the extremities, portal congestion, one or all, in greater or less degree, and here we have coming to our aid something in the way of heart tonics that will for a time urge on the flagging heart to continue what it has previously been doing by means of increased strength derived from increase of muscular fiber. It matters little which valve is affected, the therapeutic indications are practically same for each and all. It also matters little what form of digitalis is given, provided it be reliable. The difference in dose has more practical importance than the form in which it is given. There are now and then cases where the heart is acting tumultuously in the later stages of dilatation, the kidneys not secreting urine and the patient to all appearances approaching death, in which two, three or four large doses of digitalis, *i.e.*, an equivalent to one-half dram of the tincture, may work a transformation, after which smaller doses may be continued, always bearing in mind that while at first the drug stimulates secretion of urine, if long continued, and especially in large doses, the opposite effect may be produced. I know of no other drug that will take the place of this. Strophanthus, spartein, strychnin, etc., may be substituted, when we find it necessary to leave off the digitalis for a time, and indeed may be used as adjuvants often with great advantage.

Next to digitalis in importance in these cases of valvular disease where hypertrophy has ceased to compensate, I would place calomel, or some other form of mercury. Doubtless all the good derived from this class of drugs comes mainly from its action upon the portal system. Nearly every case of valvular disease of long standing is accompanied by a congested liver and portal system. A mercurial purge followed by the continued use of small doses of calomel, or smaller doses of corrosive sublimate, tend better than any other remedy to relieve this condition. By exercising care and judgment, this can be done in such a manner as to better the digestive apparatus rather than to impair it. Indeed, the change wrought by mercurials has sometimes been so marvelous that we have wondered if some other explanation than this action upon the portal system ought not to be offered to account for the good done. However, when we remember that this venous stasis is the forerunner of edema and ascites in all cases; that edema can not well occur

until the venous system has been obstructed at this point, we readily understand how we should expect to accomplish the great good we do by it. In those cases where we have a history of specific disease, there may possibly enter another element to account for the transformation that sometimes follows the persistent use of mercury. While I have seen mercurials used extensively for a long period of time in this disease, I have yet to see a case in which salivation, or any other unpleasant symptom, resulted from it, unless it be nausea and vomiting temporarily.

In nitro-glycerin we have a remedy that, instead of increasing the heart power as does digitalis and strophanthus, lessens the arterial tension by dilating the peripheral arterioles. Hence it is often of the greatest advantage in a crisis where by it we can take the load off the over-burdened heart, and allow it, temporarily at least, to gain its equilibrium. It acts much in the same manner that venesection does in a crisis, but with the additional advantage that the blood is not sacrificed, but remains where it can be restored to the system when the critical time has passed. It is to be remembered that to be of any great advantage, *often repeated small doses* are to be administered, and that its use is to be discontinued when its physiologic effect is shown by persistent headache.

I wish briefly to speak of another drug which I believe has not received the attention it deserves. During the last three years quite a number of chronic valvular cases in the later stages have fallen into my hands, upon which digitalis, strophanthus, nitro-glycerin and, in fact, the whole line of ordinary heart tonics, had been used until apparently all the good to be derived from them had been exhausted, and death seemed imminent. In these cases I have found *diuretin* to act beneficially. How it acts I do not know. It certainly stimulates the kidneys to better secretion, and in doing this acts better in cases where albuminuria *does not* exist. In other words, my own experience with this remedy demonstrates that the diuretic action is more marked in valvular disease of the heart than in Bright's disease of the kidneys. And in this I am not alone, as some others find the same result. In these cases that I have just mentioned as recently coming under my care, the use of diuretin in doses varying from one-half to two drams daily in divided doses, in combination with mercurials, has worked as much of a transformation as we often see by the combination of digitalis and mercurials at a much earlier stage in the disease.

THE VALUE OF THE PULMONIC SECOND SOUND.

Read in the Section on Practice of Medicine at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY J. N. HALL, M.D.

PROFESSOR OF THERAPEUTICS AND CLINICAL MEDICINE, UNIVERSITY OF COLORADO, DENVER, COLO.

My object in presenting this paper is to call attention to a well-known but much neglected subject, the investigation, in diseases of the chest especially, of the character of the second sound at the orifice of the pulmonary artery. It appears to me that many physicians, although gauging quite accurately the tension in the systemic circulation, by means of the pulse and the character of the aortic second sound, pass over as almost unworthy of notice the examination of the pulmonic area. And yet, in a few seconds, with the

stethoscope as much may be learned of the conditions of the circulation in the lungs as has been learned, at the aortic area, of the systemic circulation.

In diseases of the mitral valve, whether obstructive or regurgitant, all authorities agree as to the importance of the accentuation of the pulmonic second sound, in deciding as to the degree of obstruction in the pulmonary vessels. One may probably, with safety, go even further than most authors go, in the case of an apical systolic murmur, which has existed for some time, and say, given such a murmur, not transmitted greatly to the left, without enlargement of the cardiac area, and without accentuation of the pulmonic second sound, that probably no serious change has taken place in the valve. In other words, it is a crucial test when one is in doubt as to the character of an apical systolic murmur, and, I believe, not appreciated at its full value.

This sound is equally available in case of a mitral obstructive lesion in forming a correct judgment as to the degree of obstruction, and the degree of compensation as well. In case of doubt as to whether a presystolic murmur at the apex were due to mitral obstruction or to aortic regurgitation (Flint's murmur), the absence of marked accentuation of the pulmonic second sound would weigh decidedly in favor of the integrity of the mitral valve, although I have not found this point mentioned in any of the treatises upon this subject.

In chronic disease of the chest of whatever nature, a marked accentuation of the second sound at the pulmonic orifice is of grave prognostic import, indicating a decided obstruction to the circulation in the vessels involved, although indicating as well an hypertrophy of the right ventricle to meet the increased demand. Whether the obstruction be from the destruction of capillaries in emphysema, the contraction of the interstitial tissue in fibroid phthisis, or the combination of destruction of tissue, infiltration of the new products and possibly other processes in ordinary tuberculosis, it indicates serious trouble.

A knowledge of the value of this sign may at times save one from serious error, as in the following case, seen in consultation some years since: A girl, six years of age, had presented for five days all the rational signs of acute lobar pneumonia, but the attending physician had been unable, after repeated examinations, to locate the disease. Finally, fearing that some other trouble was setting in, he asked me to see the case with him.

After hearing the history I confidently expected to find the signs of pneumonia in the left chest, and was surprised to find the fronts entirely normal, so far as I could determine. Because of the child's weakness, it was proposed to me that the examination of the back be omitted, but, having noted a decided accentuation of the pulmonic second sound, and called the attending physician's attention to it, I insisted upon the complete examination, confident that anything of sufficient gravity to cause a decided increase in the tension in the pulmonic artery, must be discoverable upon careful examination. The back was found normal, however, with the exception of an area two inches in diameter near the lower angle of the left scapula; here very moderate dulness existed, but the auscultatory signs were marked, namely, bronchial respiration, bronchophony and moist râles. It was evidently an acute pneumonia which approached the surface of the lung only at this point, and, to one not fairly expert

in physical diagnosis, not easy to discover. I admit, of course, that no physician should overlook such signs, but they *were* overlooked by the attendant in this case, and by a previous consultant. If the two had appreciated the meaning of the decided accentuation of the sound in question, they would probably have been led to make a successful search for the cause of it.

Other instances of somewhat similar nature might be quoted, but this one will suffice for illustration.

I believe that most of the present generation of physicians in active practice were taught that the murmurs at the pulmonic orifice were not only rare, but of comparatively little importance. The effect of this teaching has been to lead many of us to entirely neglect all sounds at this orifice in ordinary examinations, for I have often seen its area passed by without so much as the touch of the stethoscope. Inasmuch as a proper idea of the amount of obstruction in the pulmonic circuit in pneumonia, and hence of the amount of work called for from the right ventricle—a most important factor in prognosis and in deciding upon the advisability of administering cardiac stimulants—can not be obtained without an examination of the sound in question; nor a correct judgment be formed, in a case of chronic bronchitis, as to whether there is beginning obstruction, and consequent hypertrophy of the right heart, from emphysema which has not yet developed sufficiently to be patent to percussion, it would seem to be proven, when the evidence we have heretofore adduced is considered, that this sound should be investigated in every day practice exactly as other accessible chest sounds are, the ease with which such examination can be made being a powerful recommendation of the procedure.

THE CARE OF CARDIAC DISEASE DURING THE QUIESCENT PERIOD.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, held at Atlanta, Ga., May 5-8, 1896.

BY LOUIS FAUGERES BISHOP, A.M., M.D.

NEW YORK.

The term "care of disease" is a very pleasing one as representing one of the most honorable offices of the physician. The old Homeric definition of the physician as the one who cured internal diseases and took care of that which he could not cure, always seemed very happy especially when coupled with the definition of the surgeon as the one who cured external diseases. It is a very practical question, indeed, how we shall manage cases of organic cardiac disease so that the patient may enjoy a prolonged and comfortable existence.

A great change of public and professional opinion as to the grave prognosis, which was formerly given in valvular disease, has occurred during the present century. The old feeling was that a person with chronic heart disease was certain to die in a moderate length of time and was in constant danger of sudden death. The more careful physical examination of modern times has modified this view to a great extent, but credit must also be given to the better care of such cases. Sudden death is uncommon except in aortic insufficiency, and in cases complicated by true angina pectoris. It may be that sudden death was more common at a period in medical history when the use of digitalis was habitually abused.

Time will not allow even the consideration of pathology in a most cursory way.

We are apt to think of chronic cardiac disease as confined too strictly to the valves. This contrary to analogy of the same class of lesions in other parts of the body. When a joint becomes the seat of chronic arthritis, the connective tissue of the remainder of the limb is frequently also involved, and the muscles are often the seat of pain.

The care of cardiac disease during the quiescent period is the care of the myocardium; for the endocardium we can do but little.

The causes of hypertrophy and dilatation are important to be understood. We refer to hypertrophy which goes beyond that degree which is desirable in a heart with damaged valves. Excessive hypertrophy is best avoided by a regular hygienic life and by systematically watching for any cause which might increase the burden of the circulation, and removing it by treating the cause, or if that is not possible by the systematic use of arterial dilators.

Dilatation is that condition which the heart reaches when struggling under the burden of a circulation it can no longer maintain on account of the weakened myocardium. Instead of a firm contraction almost emptying the heart at each stroke, the systoles only partially expel the blood, and symptoms of impaired circulation are immediately evident. Dilatation is usually gradually established, occurring at intervals, for a time from a sufficient cause, and then perhaps disappearing. However, cases of acute dilatation, even in those previously unaffected by cardiac disease, are not at all uncommon. This gradual onset of dilatation is commonly brought about by overwork, anxiety, long continued excitement, intercurrent disease, or some other cause of increased cardiac strain. The study of the pulse as indicating various plans of management in the course of a cardiac case during the quiescent period is not as easy as one might suppose. If we are familiar with the case, and familiar with the personality of the particular pulse, it is easy enough to detect danger in some marked change. We have all of us seen cases of valvular disease in which a good degree of health and functional activity was carried on for a long period of time, and yet a person examining the pulse, who was not familiar with its habitual irregularity, intermittance, or permanent extreme feebleness, would give a prognosis of immediate calamity. The mere objective weakness of the heart's action apart from the signs of passive congestion should not lead to too bad a prognosis.

The question of exercise is important and interesting. Judicious exercise may bring about compensation, and prolong the period of its existence, and the deference of that time when the cardiac lesion will overbalance the power of the myocardium.

Taking our patient at the time when a valvular lesion has been the result of endocarditis or atheroma and the heart muscle has assumed successfully its additional burden the question arises in the mind of the physician, or perhaps is put by the patient, what forms of exercise shall be taken from a sense of duty, or may be indulged in for pleasure. To this question a categorical answer is not possible. We have to consider the occupation of the patient, his surroundings and his habits. Often enough his daily occupation and life will be found well suited to his condition. Such would be the case of a man whose business required a superintendence of out-door work or the

work of a factory, that is, work devoid of sudden demands of strength, and devoid of mental excitement. The other two classes are those who do not get sufficient exercise, and those who are called upon for a dangerous amount of physical exertion. Curiously enough the former often suffer as much as the latter. The patient who leads a sedentary indolent life develops very soon the lung effects of passive congestion. The blood stasis, due to the poor heart performance, is augmented by the physical stagnation which follows insufficient exercise. Thus we see early developed in these patients chronic gastritis, constipation and the train of symptoms best described as biliousness. They take cold easily and there is quickly established a chronic catarrhal tendency in the respiratory passages. For these patients systematic out-door exercise in spite of their permanent cardiac lesion is of enormous advantage. The form of exercise must be such as will be of interest to the patient, otherwise persons of this disposition will never persist in carrying it out. The introduction of the game of golf would seem to afford an unusual opportunity for just such cases. It requires movement from place to place in the open air, pleasant surroundings, and is devoid of dangerous excitement and exertion. In certain cases bicycling on level roads in quiet districts is to be recommended, but such persons must be trusted not to enter into speeding contests. Driving, walking and calisthenics with light apparatus are also suitable. The patient should be instructed as to the principles involved, that is, that the exercise should be carried on slowly, systematically and never to the point of producing dyspnea, and never under any circumstances must competitions of strength or speed be entered into. The third class of patients who carry exercise too far are often difficult to manage because frequently enough their occupation is the only source of livelihood, and can not be readily abandoned or changed. Fortunately these patients frequently develop an unexpected degree of compensation, and provided the labor is regular they may continue for many years without the final reckoning. Still the average life of such individuals is very much shortened. If possible, these patients must be trained to do their work in a deliberate manner, avoiding sudden strains, and as much as possible they must be watched carefully for the signs of failing compensation. In some instances, when no other resource seems to be available, they must be tided over at times by the use of digitalis. Provided the work is systematic, even though severe, it is extraordinary how well some of these patients get along. We have all of us seen men with nearly all the murmurs in the whole circle of valvular lesions, who carry on occupations some of us could not endure for a single day; but all of us have likewise seen the day of reckoning when these men of powerful muscular development and splendid physique, except for their cardiac lesion, have come to a state where they can hardly lift a finger without gasping for breath. So in maintaining compensation, judicious exercise is one of the most important factors.

In connection with exercise massage should be mentioned. It has been happily defined as a process in which the operator takes the exercise and the patient receives the benefit. The use of hydrotherapy to improve the general nutrition and circulation is something worthy of attention.

It is a pity that in this country, at least, it is so

difficult to obtain a proper carrying out of these measures. The advocates of hydrotherapy have so exaggerated its therapeutic value, great as it may be, that one often hesitates to subject his patients to their care. It is hoped that the time will come when properly trained persons will be available at a moderate cost to carry out hydrotherapeutic measures and not exceed the limits of their sphere. A drawback of hydrotherapy is that when carried out as it should be it will take a great deal of time. Much of the benefit is lost if a patient can not rest after bathing. The effect of a warm bath upon congested organs accompanied by gentle rubbing and followed by a period of rest in a recumbent position can not but be beneficial when carried out under proper precautions. The importance of the care of the skin aside from any special system in chronic cardiac disease is very great. The theory that dirt obstructs the pores, however pleasant to believe, is probably not true. The value of bathing as far as health is concerned is more indirect in its effect. It improves the nutrition of the skin and stimulates its action and the tone of the general circulation.

As to clothing, the whole surface of the body except the hands and face should be always enveloped by flannel, and in severe weather this should be very much heavier than is thought necessary for healthy people.

One of the first considerations when we come in contact with such a case, is the advisability of telling the patient of the existence of the condition. To my mind in the great majority of cases this is best. It requires a good deal of patience to supply the patient with a sufficient amount of knowledge to make the explanation comprehensive and free from terror. The first point is to disabuse the patient of the popular superstition that organic heart disease is a common source of sudden death. The tendency of the day to speak of death as "heart failure" exaggerates the difficulty at the present time. It may truly be said of a case of valvular disease of the heart that sudden death is not at all probable, and it might be added that it would be preferable to the long-drawn-out death by the gradual involvement of the organs from passive congestion, dyspnea and the supervention of dropsy. It is important that the patients should know that they have a damaged heart, because their coöperation is absolutely necessary in carrying out the proper regimen. The use of drugs in these cases directly stimulating the heart's action is seldom necessary. If the heart is unable to do its work by the physiologic increase of activity with the hypertrophy that naturally takes place, it is far better by absolute rest of the patient to give the heart a chance to catch up by its natural force than to whip it up to its work by drugs. Sometimes there will be cases when circumstances do not allow a cessation of the routine work of the patient. In these cases digitalis will often remove the symptoms of the heart's deficiency. When we have the coöperation of the patient a plan of existence must be laid out as free as possible from overwork, worry, over-exertion, and dissipation.

Physical labor, if not such as causes sudden strains upon the heart's action, need not be interdicted; but all causes leading to undue excitement, or such as tend to a neurasthenic condition, must be especially avoided. A person with organic cardiac disease can often perform very hard mental or even physical labor, provided it is unaccompanied by excitement or

worry. These cases do better in the country than in the city. Routine existence is more naturally attained and the purer air and quieter surroundings conduce to the even plane of existence which we are seeking.

Whatever plan of life is made, the great point is regularity. This is none the less true in the average case because now and again instances come under our notice of persons with badly damaged hearts, who lead lives of activity and excitement and accomplish a prodigious amount of labor, and still survive. These patients live longer than might be expected, but nearly all of them pay the penalty by a period of collapse and suffering. These cases of severe valvular disease, who do not submit to a proper regimen, nearly always succumb in the end, however long deferred, to the disease itself, while the others may, as far as the heart is concerned, maintain an even plane of health, and die after a very long time only from some other disease.

In the drug treatment of these chronic cases the use of iron is of great value. The tendency to anemia which exists in all chronic diseases has in this instance a very direct tendency to exaggerate the symptoms. Sometimes dyspnea is entirely relieved when the impoverished blood is brought up more nearly to par. The alimentary system must receive very careful attention. The tendency of passive congestion to produce damage is very much increased by any functional derangement. Constipation is a very great evil in these cases, and regularity of this function should be absolutely insisted upon. The means must be chosen according to the merits of each case.

Against the use of digitalis and drugs of this class in the stage of compensation we would enter a strong protest. The routine practice is now happily rare of giving digitalis on account of the presence of a murmur without regard to other necessities. Strophanthus has proved in our hands a very valuable drug in tiding over periods of failure of compensation. For long use it has not been so satisfactory as digitalis.

The use of drugs during the quiescent period must to a large extent be the drugs which we are pleased to call "hygienic" drugs, namely tonics, laxatives, and occasionally alteratives. Strychnin is at times indicated in nearly all of these cases. It stimulates the nervous system in every part of the body, and in that way affects favorably the functions of nutrition, motion and secretion. Digitalis may be used at times when the circulation seems to overburden the heart and when for any reason the better remedy, rest, can not be applied. In chronic heart disease in individuals with specific taint, occasionally brilliant results have been obtained by specific treatment, the heart tone being apparently much improved under the course of medication.

The occasional use of mercurial purges in patients with chronic cardiac disease, who habitually overeat, is very important.

The use of alcohol in chronic heart disease is often baneful in its effects, and it is extremely difficult for the patient to break the habit. In the ordinary drunkard it is really the heart that cries out for alcohol when an attempt is made to stop its use, though the effects of the depressed heart are referred to the stomach, brain and general circulation.

The habitual use of alcohol is also to be discouraged on the ground of causing unnecessary exhaustion of the heart muscle and a tendency to tissue degeneration throughout the body. It is to be remembered

that fat is as often an indication of misdirected nutrition or degeneration as it is of hypernutrition. On the other hand in emergencies there is no drug so useful as alcohol in developing quickly and strongly, and at the necessary moment, the latent powers of the heart.

A discussion of the management of chronic heart cases would not be complete at this time without some reference to the influence of thyroid activity upon the heart's action. Without going into a full discussion of the probable fact that exophthalmic goitre is due to a hyposecretion of thyroid products, and that many conditions resembling obesity with its accompanying sluggishness of heart's action and tissue metabolism are to some extent dependent upon an under secretion upon the part of the thyroid, we can not but feel like administering the thyroid gland, at least in an experimental way, to those cases of chronic heart disease in which the heart as a whole and the heart fibers seem to be impaired in their action by fat. One of the most distressing complications of chronic cardiac disease are the attacks of pain, whether or not we dignify these attacks by the name "angina pectoris." The treatment of the attacks when they occur is not to be discussed here. The patients who seem to be liable to such attacks should often systematically take iodid of potassium.

While we have gone over at some length the considerations which are to be reviewed in forming a plan of management for each case, still much remains for the domain of individual judgment. In these patients much must be considered besides the actual objective symptoms at the time of the examination. Hereditary tendencies are a factor which must never be overlooked. If several members of the patient's family have succumbed to cardiac disease at about the same period of life, it is always a grave element in prognosis. That mysterious force, or rather storehouse, which we call latent energy, can not be fathomed and its capacity estimated with any degree of certainty. We have all of us seen patients who had apparently reached a state where compensation seemed impossible, gradually climb to a state of fair health and comfort. We have also seen patients who had gone on well for a long period of time, without apparent cause, suffer a loss of balance and perhaps go very quickly to a fatal termination.

In emphasizing the importance of hygiene in the management of cardiac disease during the quiescent period there is no stronger warning than that a recurrence of valvular inflammation is sure, by extension as well as by overwork, to involve the heart muscle in a secondary degeneration. Anti-rheumatic treatment should be instituted whenever any return of inflammation is feared, and the case should, for a short time at least, be managed with absolute rest, and the bland diet suitable to the inflammatory stage.

In discussing this subject we have not considered very much the particular lesion which might be found in the valves upon examination. We can not lay down specific rules for the management of mitral insufficiency, another set of rules for mitral stenosis, though the same management would be much more efficient when the former is the predominant lesion than when the latter exerts the greater influence. We can not treat a valvular lesion directly. Our prime object is to keep nutrition of the heart as good as possible, and by this we mean the avoidance of degeneration and the avoidance of excessive hypertrophy.

The nervous mechanism of the heart, as representing the conservator of heart energy, must be treated with consideration.

It would be an interesting question to have definitely decided whether the actual volume of blood is greatly influenced by any practicable degree of dry diet. It has always seemed to us that the mechanism whereby the volume of fluid is maintained at a certain normal level was so perfect that any attempt to alter the volume of the blood by putting that mechanism on the strain must be inevitably fruitless. It is different, however, with the practical reduction of volume obtained by the use of nitro-glycerin, and such drugs, which diminish the resistance and by relaxing the smallest vessels bring about a relative reduction in the volume of blood.

In these ways and by many other little details, with the coöperation of an intelligent patient who understands thoroughly his condition, we can care for and maintain an even condition of apparent health for many years. Far more satisfactory is such a procedure than the up-hill work of the treatment when compensation has not been maintained, a contest which however much prolonged has but one final termination.

LYCOPERSICUM CARDIOPATHIA.

Read in the Section on Practice of Medicine at the Forty-seventh Annual Meeting of the American Medical Association, at Atlanta, Ga., May 5-8, 1896.

BY W. T. ENGLISH, A.M., M.D.

PROFESSOR OF PHYSICAL DIAGNOSIS IN MEDICAL DEPARTMENT OF WESTERN UNIVERSITY OF PENNSYLVANIA AND CONSULTANT IN CHEST DISEASES IN THE SOUTH SIDE HOSPITAL, PITTSBURG, PA.

The *lycopersicum esculentum*, natural order of solanaceae, indigenous to South America, is a vining plant with irregular sessated leaves, bearing fruit of various shapes and colors. It is also known as the "love apple," but more commonly is called the "tomato." It was introduced into America in the latter part of the sixteenth century as an ornamental natural curiosity, and was found only in the conservatories of the wealthy. On account of its peculiar beauty it was subsequently taken to Europe. The fruit was considered poisonous to the human, but was observed to be eaten by lower animals. This fact excited Yankee curiosity and it was tested and adopted as an article of diet in some sections of America. It was not until the beginning of the civil war that its acceptance as an edible food became general. Europe has not up to the present given it general welcome as a food. Its principle utility is that of a relish and an agreeable addition to sauces. However, some people regard it as a wholesome and desirable acquisition to the list of foods. Because of its low nutritive value it does not merit a place with substantive aliment. Analyses have placed it among the vegetables consisting of over 85 per cent. water. According to Chambers and other writers on dietetics it is a diluent and not a food. The fluid element has been found to consist of an acid, called by some *acidum lycopersicum*. Others have claimed the acids to be acetic and malic in combination. Notwithstanding the almost universal indulgence in this fruit there is a certain proportion to whom it acts as a poison. In some the symptoms are gradually developed; in others they become immediately alarming. Some cases show no immediate evidences, but the results are cumulative. Once the abnormalities appear they are liable to continue to increase as long as the fruit is ingested. Even in

those, who for a time abstain, it is observed that the hiatus in the symptoms does not diminish susceptibility, but that the organ influenced retains it in the same degree as when the habit was omitted; and, that, despite apparently normal findings, it is proven that there is engendered an abnormal hypersensitive condition in the heart and circulatory apparatus; and if the toxic effects are once experienced they are more easily excited thereafter. First it appears as a simple cardiac irritability, but persisted in, it assumes the character of a latent endocarditis and endoarteritis favoring the deposition of the products of inflammation throughout the circulatory apparatus, but more especially about the aortic roots and valves. The circulatory tubes, as well as the central organ, contribute to the concomitant faulty functionation so that perturbation of circulation and organic changes constitute the zenith point appropriately denominated *lycopersicum cardiopathia*. It is in the direction of the heart and circulation that the tomato habit exerts its ill effects. In early stages, in most cases, little abnormality can be found, but the apparent relation of cause to effect is empirically determined. The heart passes out of the condition of equilibrium into a habit of irregularity and inequality of rhythm and force. Dyspnea supervenes, limiting the capacity for exertion. Age and sex are influential factors. Adolescence and puberty with their new obligations make these periods especially liable. Heart development adds a new impetus to the irritation. The aged with the circulatory apparatus already upon the verge of change readily receive the initiative thus extended. Women during pregnancy and also at their menopause are often among those who exhibit the most severe and immediate results. In many maladies there is a peculiar pathology belonging to the rich man because of excesses, and on account of poverty and self-denial the poor man has his peculiar ills, but the tomato cachexia fastens itself upon each with the same hostile grasp.

Doubtless many cases of the tomato heart occur among those who are susceptible to a marked degree, and this sensitive condition permits the disturbance to augment in geometric rather than in arithmetic ratio. This predisposition aids in establishing a pathologic modality, which is readily observed to be a factor. But there is a growing sensitiveness noted at each succeeding alarm, until the body betrays its sympathy with the heart and circulation. But again there are those from whom the suffering line is very far removed and to whom even sentimental fears are distributed with extreme parsimony. These different neurosal types constitute the extremes in these cases.

Among the pathologic phenomena that appeal to us are the acidulous conditions of the stomach and the bodily fluids. With this state of the fluids there is a concomitant lowered alkalescence of the blood. The blood pressure is high because of the peripheral vasomotor contractions incident upon the variations in the blood of reduced alkalinity. The subendocardial ganglia also feel its influence directly applied to the sensitive endocardium. The ganglia in the muscular substance are brought into intimate relations with the blood through the medium of the coronary arteries and their branches and these are likewise perturbed.

High blood pressure excites the heart to vigorous action and causes a spastic rather than a paralytic condition. Myocardial weariness is induced and corresponds with the excitement as to degree and persistence.

Because of the irregular and spasmodic stimulation of the ganglionic cells there is a gradual deterioration in nutrition, beginning primarily with the trophic nerves and extending its pernicious influence to the other nerve supplies, materially damaging the cardiac enervation and begetting irregular action. At each succeeding paroxysm of palpitation there is noticed an increased inability to adjust the errors existing between blood pressure and heart action. Each paroxysm becomes easier of precipitation, and although the individual is more accustomed to the turbulence, the alarm and sensation are on the increase. The perfect functionation of the heart is held in abeyance by the continuous ingestion of the tomato, and the irritation becomes chronic. When long continued there are organic changes introduced, the tomato habit acting primarily as an irritant and later becoming an excitant to the already abnormally irritated organs. The left ventricle being more sensitive than the right, it is impelled to a premature attempt at systole, causing irregular rhythm, and this, together with the overfilling of the capillary pulmonary circulation produces a prodromal asthma, which remains prodromal only so long as the heart maintains its unchanged structure.

Observations have been conducted over fifteen years and experience assures me that at least one-half of those who use them suffer more or less, while one-fourth are obviously injured. A small percentage exhibits all the evidences of acute poisoning.

The symptoms first noted are those of the immediate effects of acidum lycopersicum upon the stomach and *prima via*. Pain and gastric uneasiness are succeeded by burning, choking, pyrosis and heartburn. These are succeeded by acid eructations with gaseous emanations from the stomach and, in some cases, vomiting.

Borborygma and active peristalsis are the enteric announcements, and these are speedily succeeded by stools of fermentative and offensive character. Eructations or expulsions of intestinal gases give temporary relief to the asthmatic oppressions, which proves that mechanical distention has something to do with the symptom of dyspnea. The appetite is usually good until the onset of these symptoms, when the desire for food is supplanted by a craving for drink, which is the result of irritation, or congestion, of the gastric mucous surfaces. There are some cases in which these local symptoms are pronounced immediately after the ingestion of the fruit. The matter vomited is acid and of an odor betraying fermentative action. The excretions are acid, and the emunctories are usually very active.

Rapidly following these local phenomena pertaining to the digestive tract there is a rise in blood pressure proven by sphygmographic tracings. If the pressure is already high, it will be still higher. The tactile sense appreciates it in the apex beat and the pulse.

One of the most constant symptoms of the tomato malady is the sighing respiration. The missing heart beat or the half executed circulatory cycle conveys to the patient the startling announcement that there is a serious and sudden arrest of vital activity within the thorax and it creates in the psychologic function as well as in the conceptions of the mind an uncomfortable surprise. The gap in the circulation is associated with a spasm of the respiratory function and a gasp for breath is the effort for relief. The patient's mental, moral and physical sympathy is

aroused with as much earnestness as if he were receiving the immediate herald of impending death. Unlike the habitual mountain climber's heart and respiratory organs, the tomato habit observes no quietus from custom, but at each return the irritation seems to find more sensation and prompter response. If the paroxysmal palpitation reaches its typical acme, as in the very acute forms, the distress and anxiety are so pronounced that they approach all the terrors of true angina pectoris. Cold sweats appear upon the forehead and there is an imaginary intensity in the symptoms of bodily and heart fright, which steals over the patient's senses, that can not be measured by comparison with those which are real. The fluttering and fullness in the precordial region continue after the subsidence of the violence of the paroxysm, and are associated with cephalalgia, supra-orbital tension and a constitutional languor. In acute cases speech is greatly impeded and articulation at times almost impossible, though there is never complete aphasia. Together with this indistinct enunciation there is occasionally an incoherence of thought and several ideas seem to seek expression at the same time. Disturbed vision, floating objects in the visual field, beating and singing in the ears, giddiness, mental apparitions, numbness of the fingers and tongue, and general perversion of the senses, constitute a part of the neurosal procession.

Some marked cases have been observed by me, which have presented a complete panorama of these symptoms within two hours after the ingestion of tomatoes. A number of patients are under my observation upon whom these symptoms can be reproduced within two or three hours after introducing into the stomach two ounces of tomato fruit. Immediately in some cases the irritation of the peripheral nerve terminations in the stomach produces a species of nervous cyclone, or a little nerve storm in the heart and its intrinsic ganglia. The symptoms which have arisen after the ingestion of tomatoes in the presence of preëxisting heart maladies have been deplorable, and have been introductory to, if not the immediate prodromata of death. In weakness of the respiratory muscles there will be corresponding augmentation of attending distress. In emaciated persons or those reduced by poverty or loss of blood the symptoms of palpitation are precipitated with alarming celerity. The use of tomatoes as an article of diet among pregnant women is followed by tumultuous demeanor of the heart, and where predisposition to abortion obtains may produce hapless results.

During the developmental period of the heart—especially that marking the rapid increase in cardiac growth between adolescence and maturity—the tomato should be discarded as likely to occasion unpleasant symptoms and precipitate evil. The period when it seems foolhardy for women to use this fruit is at the climacteric, on account of the abnormal cardiac phenomena they excite and the disposition to inflame preëxisting nervous irritability.

The diagnosis of the disorder propria is usually not difficult, if we are once rid of the preconceived notions with which the symptoms enumerated have been connected. One is likely to fall into the habit of estimating by former and more familiar standards. Some effort will become necessary to disassociate them from dyspeptic symptoms and phenomena connected with cardiac lesions. This need becomes the more urgent to my mind, when I recall the fact that of the

heart maladies sent to me for diagnosis, a large percentage are functional and fully one-half of these are due to the tomato habit. When once pointed out, however, these cases can scarcely be overlooked or their symptoms confounded. The history will aid us, and if one attack does not satisfy our mental questioning, there will be little loss of time until another opportunity is secured to indulge in a second observation, as patients are loath to accept the theory of tomato poisoning; and under any circumstance humanity, including the medical man, is slow to acquiesce in anything which limits dietetic privileges. While the picture presented may not be as complete as the present aspect of medical inquiry demands, it is as conscientious and faithful as I can at present give.

The best treatment is to abstain from the use of tomatoes. During a paroxysm, and immediately succeeding one, it is needful to employ an antidote to the toxic conditions. This agent should include the capacity to annul the irritation that is local to the stomach and prima via, as well as to place a quietus upon the neurosal storm which is usually present in the acute form of the malady. This agent is acetanilid, one of the coal tar products; and it is always applicable, except in the chronic cases attended with heart degeneration. The following prescription is as perfect an antidote to lycopersicum poisoning as I have discovered:

R Acetanilid 5ij 8
 Spr. vini rect. 3ij 64

Misc. Sig. Teaspoonful in water hourly until three doses are taken, thereafter every eight or ten hours.

This clears the vision, restores the wandering senses and rapidly places the organs within range of their lost tonicity. On its exhibition there is almost immediately a clarification of the visual and mental fields, and a return, within an hour after the first or second dose, to a desirable circulatory and respiratory calm. Some slighter neurosal phenomena as tremor and general depressions are more deliberate in their leave taking.

Antacid diuretics are needful to divest the bodily fluid of the influence of acidum lycopersicum. Quiet and general hygienic restrictions are always commendable.

There is a peculiar virulence to acidum lycopersicum that can not easily be overpowered, and its effects remain apparent in the stomach and intestines for some days, despite the use of alkalin purges and occasional draughts of lime or potash water. The use of disinfectants is to be commended, as of creosote, charcoal, etc. Observations of the patient's diet are necessary in a special way. The most wholesome articles of diet in ordinary conditions must, in many of these cases, be avoided. Milk is not admissible immediately after, or during an attack, as it forms into a substantial curd and is totally undigested. Eggs are rendered rancid. The diet should be restricted to light foods and those easy of digestion, and this restriction should be continued for at least one week. Tonics and supports for the offended nervous system are to be employed, and when greatly irritated they demand sedative treatment. The former may be secured by the administration of strychnia. The latter is accomplished by the use of chloral or the bromids. Chloral acts well if the patient is persistently somnolent.

The circulatory changes involving myocardial

degeneration or including sclerosis of the tubes will suggest recourse to special cardiac support and remedial agents.

To a number of medical men I owe my thanks for faithful observations, and the record of facts associated with the use of the *lycopersicum esculentum* in public institutions, hospitals and alms houses, which I can not detail here.

Personal experiences are in my possession, delivered orally and in writing by those who have individually noted the deleterious effect of the acute attacks as exemplified in their own bodies and which are not within the scope of this paper to recite. They, however, suffice to prove the tenable ground upon which this theory is based. General depression is reported to have been a common sequence to their employment in one of the alms houses near Pittsburg and also in several of the hospitals in the vicinity. Many of those who were in health were reported as being depressed, while the ill were rendered worse after their use. This would lead us to the conclusion that those in charge of hospitals, alms houses and other charitable institutions in which they are employed should expunge them from the list of foods.

The supplies for the military should never include this vegetable, as it has been abundantly proved that it can not be for the physical good of the men or subserve the interests of hygienic and economic food supply.

At any time when any great mental or bodily endurance is required, the tomato is treacherous and can not be relied upon as a food. When some acute loss or bereavement occasions emotional influences that call for cardiac reserve force, and under all circumstances where fortitude is demanded, the ingestion of tomatoes is to be discouraged. Those who are called upon to endure loss of sleep or mental strain, the student, the speaker or the statesman, will find them worse than useless.

DISCUSSION.

DR. PAUL PAQUIN, St. Louis—I never before knew that tomatoes were injurious to mankind. According to the paper, I should have been dead ten years ago, and I doubt if many of us would remain in good health. I remember when the tomato was not used at all as an article of diet, but since then it certainly has been used very extensively, and I had never before supposed that there was anything poisonous about it. But I would like to know if we are still to have some other kinds of heart. We have a tobacco heart, we have the onion breath; probably we will have a carrot heart, and a potato heart. I doubt, indeed, if we will ever be able to make a list of the vegetables which we may eat safely. Are not some of the results attributed by the author to eating tomatoes produced by eating anything, almost? I would like to know on what scientific investigation it has been discovered that the tomato is a baneful enemy of mankind.

DR. HILL, Milwaukee—I wish to say that in my opinion the symptoms which he has ascribed to the tomato are the result of wind on the stomach—being the direct effect of fermentation. I wish to call attention also to one other fact, that is, that in rural districts where the tomato is grown and ripened on the vines these results are not often observed; that it is not only not harmful, but that it acts as a most excellent regulator of the bowels and an excellent article of diet. But in cities the tomato, like all other fruits, has been of necessity shipped in the green state and not allowed to ripen by nature's process, but by the process of putrefaction, which continues in the stomach, and if used in large quantity it produces fermentative change and the results named in the paper. One other remark; it concerns his treatment. It is the use of two drugs diametrically opposed to each other, one a cardiac depressant, the other a cardiac stimulant—acetanilid and alcohol. I would suggest that it is rather to the alcohol that the relief is due, because the alcohol given in that form, although not quite as efficient as the aromatic spirits of ammonia, acts as a stomachic,

relieving the stomach of its gases by stimulating the action of the muscular fibers and increasing peristalsis, as well as incidentally stimulating the heart.

DR. J. W. GROSVENOR, New York—I would ask the reader if he knows what the toxic agent is that produces these dire results. Have any chemical studies been made to show what the toxic principle is?

THE CHAIRMAN, DR. QUINE, reminded Dr. Grosvenor that it had been suggested in the paper that the toxic agent was *acidum lycopersicum*.

DR. ENGLISH—Dr. Hill, who has called attention to the fact that my prescription is incompatible physiologically, is certainly correct, and its very incompatibility is the very essence of it. In the first place it contains acetanilid, an anti-acid, which has a corrective action on the conditions in the stomach generated by the tomato, but at the same time depresses the heart. It is necessary to support the heart by the use of alcohol. It is the proper way to employ acetanilid unless you want to employ it for its depressing effects.

THE EFFECT OF ALCOHOL ON THE ORGANS OF SPECIAL SENSE.

Read in the Section on Practice of Medicine, at the Forty-seventh Annual Meeting of the American Medical Association, Atlanta, Ga., May 5-8, 1896.

BY J. W. GROSVENOR, M.D.

NEW YORK.

No extended argument is needed to demonstrate the effect on the organs of special sense¹ of alcohol in large quantities, sufficiently large to destroy temporarily the functions of these organs.

Any person in the condition in which he may be properly called "dead drunk" is completely narcotized. His entire nervous system is paralyzed. He may have taken a half pint or a pint of whisky or brandy. Either of these amounts is a large quantity, the former for a child, the latter for an adult.

The person overcome by a complete alcoholic stupor has lost for the time being the functions of the special senses. Speak in stentorian voice to the victim of such a condition and he gives no sign of the existence of the sense of hearing; expose his eyeballs to a bright light and the pupils give no response to indicate the presence of vision; prick and cut the body with a sharp instrument and he manifests no sense of feeling; place the most pungent volatile substances near his nostrils and you observe no suggestion that they painfully affect the olfactory nerves. He is as profoundly narcotized as though he were fully under the influence of ether or chloroform.

The person who has taken an alcoholic drink in quantity sufficient to place him under its positive influence though not sufficient to profoundly narcotize him, who is able to control his acts to a considerable extent suffers in his organs of special sense in like manner, though not to the same degree, as the person whom it has completely overwhelmed with narcotism.

Hearing is lessened, as evidenced by the fact that a much louder voice than ordinary is necessary in order to attract the attention; such a person on the street for lack of normal vision frequently comes in contact with a post or another person; the sense of feeling is blunted, since he may fall and bruise himself severely without complaint of injury or pain; or he will drink a glass of rum, brandy or whisky without observing the caustic effect usually produced upon the mucous membrane of throat and stomach.

It is a well-established fact that the sense of sight is permanently injured by the excessive use of alcohol. Amblyopia alcoholica is noticeable in the early stage of alcoholism. The disease advances or recedes

¹ Special attention is directed in this paper to the senses of seeing, feeling, hearing and weight.

according as the amount of alcohol taken is increased or diminished. The pathologic factor of the disease is an interstitial neuritis, proliferation of connective tissue followed by degenerative atrophy of the optic nerve. This disease has been clearly described by Dr. Charles H. May. (*The Medical Temperance Journal*, July, 1891, taken from *Quarterly Journal of Inebriety*.)

The effects upon the organs of special sense of extremely large and moderate quantities of alcohol as stated above have been recognized by common observation ever since the discovery of this substance several centuries ago. Among physiologists and therapeutists of the present day there appears to be no very marked difference of opinion as to the most prominent effects of alcohol upon the human organs when taken internally in large quantities.

It is acknowledged to be an anesthetic, a paralyzer. Opinions widely diverge, however, as to its effects when taken in small or minute quantities.

The effect of exceedingly moderate or minute quantities of alcohol upon some of the organs of special sense has been demonstrated by carefully conducted experiments. Of all scientists, perhaps no one has wrought more thoroughly and satisfactorily in this field than Dr. J. J. Ridge, of London, England. For the purpose of determining the effect of small doses of alcohol upon the sense of feeling he used an instrument which is best described in his own words:

"An instrument was constructed in which were two points in an upright position, and about half an inch apart. A third upright point was situated between the two, and was capable of being moved in a straight line nearer to one or the other of the stationary points. These three points were covered in so as to be invisible, but the forefinger could be passed through a hole in order to feel them. The middle point was moved by a rack and pinion, and the person tested was required to move it until, in his opinion, it was as nearly as possible equally distant from the two outside points. The movement of the middle point was recorded on a dial invisible to the subject of the experiment. This form of instrument was preferred to the ordinary esthesiometer, because in that instrument (in using which the person has to state the earliest moment that he can distinguish the points of a pair of compasses or two, while they are gradually separated) imagination might more easily vitiate the conclusions."

The results of his experimental researches made upon the sense of feeling, with the instrument above described, are embodied in the following table:

FEELING.

Ab. abstainer.	Number of degrees on the dial from exact center before alcohol.				Average.	Number of degrees on the dial from exact center after alcohol.				Average.	Amount of absolute alcohol given.
Ab...	6	6	3			5	10	8	10	9.3	2 drams
Ab...	6	30	4	30	16	16	20	24	46	28.	2 drams

Ab...	75				75	115				115.	2 drams
					115					189.8	

The quantity of alcohol, two drams, given to each individual tested may reasonably be regarded as quite small. Five abstainers were tested, the total number of tests being fourteen *before* and the same number *after* alcohol was given. The average number of degrees on the dial from the exact center *before* taking

the alcohol was 23; *after* taking the alcohol 38. The smaller number represents the greater sensitiveness of feeling or touch.

This may not be regarded as a great difference, but it is a difference that is positive and shows that so small a quantity of alcohol as two drams may sensibly affect the nerves of feeling and decrease their sensitiveness.

The effect of small doses of alcohol upon the sense of vision was tested by Dr. Ridge as described by himself as follows: "Vision was tested by noting the distance at which a row of letters could be read with one eye without alcohol, and then the distance at which the same letters differently arranged could be read with the same eye afterward. The distance varies very greatly in different individuals; but of course in the same individual it would remain the same, provided that the alcohol had no effect. Indeed, one might naturally expect a slight improvement in the latter trials, by reason of the fancy letters employed. The following table gives the results obtained:

VISION.

Ab. abstainer.	Distance of distinct vision in feet before alcohol.				Average.	Distance of distinct vision in feet after alcohol.				Average.	Amount of absolute alcohol given.
Ab.	7	7.25	7	6	6.81	7	6.75	6.50	5.75	6.50	½ dram
Non-Ab.	9	7	7	8.5	7.87	8.75	6.75	5.75	8	7.31	1 dram
Ab.	10.50	10.75	10.5	10.5	10.56	8	9	7.5	9.50	8.50	1 dram
Non-Ab.	4.25	5.25	5.25		4.91	4.50	4.50	4.25		4.41	2 drams
Ab.	10.25	9	7.25		8.83	9	9.25	8		8.75	2 drams
Ab.	11.25	11.25	10.25	9.5	10.56	10.50	10.50	11	8.50	10.12	2 drams
Ab.	15	10.5	13		12.80	13	10.50	12		11.80	2 drams
Ab.	9.25	10	25		9.75	8.50	8			8.25	4 drams
Ab.	6	6	5.75		5.91	5.25	4.75	4.75		4.91	4 drams
Ab.	16	15.5	15.75		15.75	14.75	14.50	15.25		14.83	4 drams
					93.75					85.38	

General average—9.375 before; 8.538 after."

Ten individuals were tested, eight abstainers and two non-abstainers. Thirty-three trials were made before the ingestion of alcohol and the same number after its ingestion. The average number of feet at which the letters could be read before taking the alcohol was 9.375, after taking it 8.538. Expressed in inches the difference was 10.044. This number represents that on the average the individuals tested, in order to see the letters distinctly, were obliged after taking the alcohol to approach 10.044 inches nearer to them than before taking it.

One of the individuals took ½ dram, two others 1 dram each, four others 2 drams each, three others 4 drams each. In the case of each individual the average of his tests showed that his vision was decreased in from fifteen to thirty minutes after taking the alcohol.

The average difference in the vision point before and after the alcohol doses in the majority of cases was not very large; indeed, in some of them it was quite small. In one it was more than two feet, which is 19.50 per cent. of the larger distance. The average of all the tests showed that it was necessary to shorten nearly 9 per cent. after taking alcohol the distance between the vision point and the letters before taking it. Derangement of vision, in the form of hallucinations, is recognized as an every-day occurrence in cases of acute alcoholic delirium, the sight of strange things and living creatures that can not possibly exist at the time within the range of vision.

The same experimenter, Dr. Ridge, tested the muscular sense of weight before and after the ingestion of small quantities of alcohol. He has thus described his method of procedure:

"The amount of muscular force required to overcome different resistances is measured by a special sense connected with the muscles but exercised by the nerves. Comparison between two weights requires the action of the judgment. The more acute the perceptive faculties are, so much the more readily will the judgment decide upon small differences between two weights. The effect of alcohol on this muscular sense was determined by an arrangement in which a weight was attached to a certain lever, and the person experimented upon was required to slide an equal weight along another lever exactly similar to the first until, in his opinion, the weights appeared to be the same. It is obvious that the position of the weights on each lever ought to be exactly the same and, therefore, the more sensitive the muscular sense is the nearer will the individual be able to place them before he ceases to detect any difference." The following table gives an exhibit of his results:

WEIGHT.

Ab. abstain'rs.	Distance between the weights, in millimeters before alcohol.				Distance between the weights, in millimeters, after alcohol.				Average.	Amount of absolute alcohol given.	
Ab.	14	8			11	7	20		13.50	1/2 dram	
Non-Ab.	22	10	16	18	16.50	18	20	22	20	1 dram	
Ab.	3	4	2	10	4.75	8	4	8	5.75	1 dram	
Ab.	4.5	7	9	7	6.90	13	11	12.5	13.50	2 drams	
Ab.	2	2	9	5	4	5	4	13	8	2 drams	
Non-Ab.	2	4	5	2	3.25	10	4	6	6	2 drams	
Ab.	2	2	5		2.25	1	7	4	3.75	2 drams	
Ab.	5	7	9		5.25	10	8	8	6.50	2 drams	
Ab.	9	1	11	1	4.40	3	8	11	8.20	2 drams	
Non-Ab.	2	3	4	1	2.50	6	6	8	5.75	4 drams	
									60.60		90 95

General average—6.060 before; 9.095 after.

Dr. Ridge thus sums up his tests upon the muscular sense of weight:

"From this table certain facts are apparent: 1, that in every case the average sensibility to weight and power of discrimination was decidedly diminished by small doses of alcohol, the general average indicating that the sensibility is diminished about one-third; 2, that single trials are not reliable, since many circumstances may unite to produce a fallacious result. Thus some of the trials after alcohol were actually more accurate than some of those before it, although the average of each individual conforms to the general average of the whole; 3, that non-abstainers are affected, as well as abstainers; 4, that small doses act in a similar way to large doses, and that the difference is only in degree, not in kind."

The deceptive nature of alcohol was observed in all these experiments. Each person tested was confident that his powers were equal to the accomplishment of more than scientific experiment showed was possible. This fact teaches that the alcoholic drinker's assertions as to the integrity of his special senses are not reliable. His organs of special sense may have lost a considerable portion of their natural powers and he may still be unaware of this condition.

Experiments made by Dr. Seougal upon the sense of hearing show that alcohol in small quantities affects this special sense in the same way as the other organs of special sense are affected by it.

Dr. T. D. Crothers has made simple tests of the sense of hearing and has arrived at similar conclusions.

In cases of alcoholic insanity the sense of hearing is frequently disordered. In this form of insanity the

occurrence of hallucinations of hearing has been noted often by those who have the care of the insane; unusual voices and sounds that at the time have been beyond the reach of normal hearing. Aural and visual hallucinations have led to many fatal assaults upon supposed enemies, the assailants believing that the false impressions received through the senses of sight and hearing were true.

Some observers have noted in cases of alcoholism that the special senses suffer occasionally in one half of the body; there is loss of sight of one eye, hearing of one ear, taste of one half of the tongue and smell of one nostril.

The results of these experiments declare in unequivocal language that alcohol in small or extremely moderate doses weakens the nervous supply of the organs of feeling, seeing, hearing and weight; that to a certain extent it paralyzes these special senses.

According to Dr. Ridge, "Dr. Lionel Beale long ago pointed out how it (alcohol) affected the protoplasm of cells and diminished the movements of amebae, to which leucocytes are apparently analogous." Dr. Ridge has found that the action of alcohol on leucocytes is injurious. His experiments with plants show that they do not thrive when watered with water which contains half of one per cent. of alcohol; that thus vegetable protoplasm is materially injured. The vegetable cell is not so very different from the animal cell as to prohibit the belief that if the protoplasm of the former is injured by minute doses of alcohol, that of the latter is affected in a similar manner.

Dr. Ridge has also discovered that alcohol in almost incredibly small quantities will promote "the growth and multiplication of microbes whose function is antagonistic to the protoplasm of organized beings." "In the presence of these minute quantities of alcohol decomposition goes on more rapidly and the micrococci and bacilli thrive and swarm more abundantly." He has thus shown that alcohol in the minutest quantities is injurious to "constructive protoplasm" and favorable to "destructive protoplasm."

Without doubt the protoplasmic nerve cells of the organs of special sense are as sensibly affected by alcohol as the cells of any other tissues of the body. Consequently the effect of minute quantities of alcohol on both vegetable and animal cells is a strong argument that it injures the constructive protoplasm and favors the destructive protoplasm of the organs of special sense.

Dr. Prout's experiments made more than eighty years ago proved that alcohol in a small or moderate quantity lessened the amount of carbonic acid exhaled from the system. More than a physiologic amount remained in the system to act as a poison upon the tissues and fluids. From this result the legitimate conclusion can be drawn that the special senses would suffer their share of injury.

It is a fact well-known that the long and excessive use of alcohol internally has a degenerating influence upon nearly all the solids and fluids of the body. This is quite noticeably true of the nervous and circulatory systems. Growing cells become deteriorated, tissues are hardened, blood loses a part of its vitalizing elements. It is not unreasonable to believe that as the whole system is burdened with this "genius of degeneration," alcohol, the organs of special sense must bear their proportion of the burden.

During the last few years railroad managers have

observed the injurious effect of alcohol upon their workmen when occupying positions that require delicacy of touch, keenness of vision and acuteness of hearing. Not long since a large railroad corporation investigated the conditions surrounding every accident that had occurred on its lines during the preceding five years. It was found that 40 per cent. of all accidents were due entirely or in part to drinking men. In 18 per cent. it was strongly suspected that the drinking habits of employees was the cause of the accidents. The company in a single year lost property to the amount of one million dollars through the incompetency of beer-drinking engineers and switchmen.

Michigan has passed a law which imposes a heavy penalty upon those railroad companies which employ men who are in the habit of using alcoholic intoxicants. Railroad managers, as practical business men, are recognizing the utility of employing total abstainers as a measure calculated to reduce financial losses on account of accidents.

Some railroad companies prohibit their employees from drinking any kind of intoxicants and from entering a drinking saloon during working hours; other railroad companies demand from their employees the signing of a total abstinence pledge which shall hold good for every hour of every day.

This action of railroad managers shows their appreciation of the doctrine that even small quantities of alcohol impair the organs of special sense, and that in order to do the best work in railroad business the workman must have eyes, ears and hands perfectly free from the poisonous touch of alcohol.

From the experiments and investigations herein detailed we are warranted in drawing the conclusion that alcohol in small quantities does not act upon the organs of special sense as a stimulant, but as a depressant; not as an energizer, but as a paralyzer. The claim that alcohol in any quantity strengthens and sharpens the vision, the touch, the hearing, has no defensible foundation for its support.

If these conclusions are reasonable concerning that part of the nervous system that supplies the organs of special sense, may we not assert with reasonable certainty that the same result obtains in other and, indeed, in all other parts of the body? Surely the nervous cells are not so very unlike in different parts of the organism as to forbid this conclusion.

Neither does alcohol in small doses differ in quality from alcohol in large doses. One drop of it has the same characteristics as a thousand drops. The large quantity produces a more powerful effect than the small quantity, but in kind the effect is the same.

In the study of this subject some of the thoughts which have been forced upon my attention are as follows:

1. Guided by the chief characteristic of alcohol, its paralyzing influence, is it not more appropriate to call it a depressant than a stimulant?

2. If alcohol becomes popularly known as a depressant, will it not be less frequently used by the laity in those physical conditions which are commonly supposed to demand stimulation?

3. Knowing that alcohol is a depressant even when given in small doses, ought not the medical profession to exercise great care in administering it in debilitated states of the system?

4. The use of alcoholics hypodermically in cases of heart failure or arrest of respiration caused by ether or chloroform narcosis is bad practice.

5. It is the duty of the medical profession of this country, clearly and fully comprehending not only the damage to the organs of special sense, but also the ravages upon all the important organs of the body caused by alcohol, to discourage by every laudable effort the habit of drinking alcoholic intoxicants, to the end that our national life may be characterized by physical and moral integrity, clear brains, steady hands and brave hearts.

DISCUSSION.

DR. G. W. WEBSTER, Chicago—I have yet to find any form of illness or sickness, or any condition of health, where alcohol in any dose acts as a stimulant, as we understand the word stimulant. Not that I wish to be understood as objecting to the use of alcohol in its proper sphere, but it is never, under any circumstances nor in any dose, a stimulant. There is not one particle of evidence with which I am acquainted based upon careful observations, that will for one moment justify us in stating that alcohol is, in any dose or in any sense, a stimulant. It is, in all doses and under all circumstances, a depressant, an anesthetic.

DR. YAGER, Kentucky—I speak now of this subject in a medical sense, and wish to endorse to a great extent what Dr. Grosvenor has said. While I give whisky in sickness, I have not touched a dram of it myself, but became its opponent from a moral sense.

DR. H. A. HARE, Philadelphia—If it is possible for anyone to say that there is no evidence that alcohol acts as a stimulant, it is perfectly possible for it also to be said that the world does not go round. Now, you may bring every citizen of Atlanta into this room who knows anything at all about the matter, and he will tell you that under some circumstances alcohol does act as a stimulant, and how it is possible for any physician who has used alcohol properly in the treatment of disease to say that under certain circumstances it does not act as a stimulant, is to me most extraordinary. I have had a very large hospital experience, and have had the opportunity of watching the use of alcohol, not only in my own hands and in the hands of my colleagues, but in the hands of the most celebrated therapeutists of the world, and I repeat that alcohol acts distinctly as a stimulant. Furthermore, I wish, in this connection, to call the attention of this Section to what I believe to be the great danger of medicine at the present time. We are too fond either of saying that a remedy will cure every case of a certain disease, or that it is absolutely useless in all cases of that disease. I do not want anybody to think it is my custom to teach that alcohol is always, under all circumstances, a stimulant; but on the other hand, I do not want it thought that I regard alcohol as a depressant at all times and in all diseases. Digitalis can not be used in every cardiac case, and the same is true of alcohol. The sensible doctor is rational in his therapeutics and fits his drug to the case.

DR. R. H. BABCOCK, Illinois—I believe that alcohol in appropriate doses is a cardiac stimulant; in too large doses, it is a cardiac depressant. My views upon alcohol are derived from my experience with it. Let me state an instance, the case of a physician whom I saw only last Saturday, who has a dilated heart, both right and left ventricles being dilated; has moderate arterial sclerosis, pulse ranges from fifty-two to sixty; who can not bear even small doses of digitalis, five drops producing shortness of breath and increased cyanosis. A moderate dose of whisky, in that patient, stimulates the heart to a pulse rate of seventy-two, the pulse becomes fuller and stronger, the color better, the patient feels exhilarated, and it is followed by no symptoms of depression. Now, if alcohol in moderate dose, the dose differs, of course, in individuals, stimulates that physician's heart to that kind of action, then I believe that alcohol in that case is a cardiac stimulant, not a depressant.

DR. JOHN A. OUCHTERLONY, Louisville—I can not say that I believe alcohol is a stimulant. I know it. Knowledge is always better than belief when we deal with matters which are capable of demonstration. I can not believe that all previous experience has been erroneous, that the great work quoted on narcotics and stimulants was a mass of nonsense. We can judge of the effects of alcohol as we judge of the effects of all other remedial agents that we are accustomed to employ in our efforts to cure disease. Alcohol in small doses, suitable to the patient, is undoubtedly a stimulant, and it is a very remarkable fact that the instincts of all nations have led them to bring forth from organic matters some form of alcoholic stimulant. That there should be universally such craving for an article which is absolutely injurious to the human economy, does not seem reasonable; on the contrary, I think that this very fact is an

indication that alcohol, according to the experience of all ages and of all nations, is a stimulant, capable of serving useful purposes, dietary and therapeutic.

DR. W. M. RICHARDS, Joliet, Ill.—I must endorse the Doctor's paper: as a stimulant, I have never yet ordered a dose of alcohol, nor have I seen an increase in the force of the heart. We do get a more rapid action of the heart, but it is simply from paralysis, not from stimulation. It simply paralyzes the capillaries, so that the heart can get rid of the blood which goes to it, and never stimulates. I have seen an athlete put up dumb-bells before taking alcohol, then wait a reasonable time after taking alcohol in order to get its effects, and try to lift them again, and he could not do it. You see a man come in cold: he takes a glass of liquor, and in a few minutes thinks he is warm. He is simply paralyzed, so that he is insensible to the effects of cold. He goes out under the influence of alcohol, feels that he is perfectly warm, sits down and freezes stiff. A man under the influence of alcohol thinks he is powerful enough to whip two men, but at the same time it requires two men to hold him up. Call that stimulation? He is simply paralyzed. I believe alcohol can be given in its place, just as you would use nitroglycerin, or any nitrite.

DR. MINOR, Ashville—I would ask the gentleman who has just sat down whether it is legitimate to draw conclusions as to the effects of alcohol from intoxicating doses. It seems to me it would be as justifiable to say, after observing the effects of eighteen grains of corrosive sublimate, that the action of mercury is always poisoning. It depends upon the amount of alcohol administered as to what effects will be produced. I see many who prescribe it indiscriminately, and I agree with those who deprecate such abuse.

DR. HARE, Philadelphia—I would like to call attention to a point of some importance, namely, the statement which has just been made that alcohol acts as a paralyzer of the capillaries; that it does not act as a stimulant; but that the increased rapidity of the heart is due to removal of pressure in front of the heart by paralysis of the capillaries. Now, I challenge that gentleman to present one jot or tittle of scientific evidence that his statement is correct. I refer again to the experiments of Cerna, of Castillo, and a number of foreign investigators as well as American, which prove beyond all doubt, as far as you can prove any scientific fact, that the administration of certain doses of alcohol, according to the size of the person or animal receiving it, produces a rise of arterial pressure and not a fall. And I can also prove by most careful scientific experiments that alcohol actually increases the quantity of heat which is manufactured in a man's body; that under its influence he will manufacture more units of heat in an hour than before he took the alcohol. And to show that I am not biased I may go on and say that at the same time alcohol increases heat production, when taken in overdoses it also increases heat dissipation, and the increase in heat dissipation is so much in excess of the increase in heat production that the temperature falls. It is not well to take an alcoholic stimulant and be exposed to cold, because, the blood goes to the surface of the body and carries with it a certain amount of warmth which is lost. When we expose our bodies to cold the peripheral capillaries become contracted, the blood rushes to the central vital organs to be kept warm by them, the subcutaneous tissue, and muscles. But in a warm room the blood again flows to the surface to carry heat with it. If we take alcohol before going into the cold, the blood which filled the inner vessels of the body, is driven out. It does not go there by paralysis of the capillaries. You do not see the peripheral capillaries congested by paralysis when a man dies. The peripheral capillaries are paralyzed by death, but does the surface become flushed and red? Not at all. It becomes white like marble. Why? Because the whole vascular system is paralyzed and the blood settles in the larger vessels. I would call the attention of the Section once more to what I claim is the fault in the whole study of therapeutics, namely, dogmatic treatment. In this instance the assertion has been made absolutely without citing a single authority, that alcohol does this or that: that alcohol paralyzes the peripheral capillaries in all diseases; that it lowers arterial pressure and acts like nitroglycerin. If the gentleman will produce facts to prove that, or if he can not, I want him to state that, in his opinion, that is the case, and not give it out as a definite scientific statement.

DR. HAINES, Ohio—It certainly has been shown, by all the gentlemen who have experimented and taught, that alcohol is a stimulant when given in proper doses and in the appropriate condition. I think we will find it has a stimulating influence, and one that can be safely relied upon in time of trouble.

DR. YAGER, Kentucky, stated that it was the universal use of alcohol which he was opposed to.

DR. JENKINS, Iowa—Whenever views on a medical subject are

expressed which are entirely antagonistic to all the experience and the teaching of the profession and of those out of the profession, there is certainly something wrong. According to clinical experience I do not believe a small dose of alcohol can be otherwise than stimulating. I can not believe that this notion advocated lately, that alcohol is a depressant, and that its action can be explained along that line is correct. I look upon alcohol, like upon many other drugs, as exceedingly dangerous, but I should hate to discontinue its use because it is capable of doing harm, just as I should hate to discontinue the use of such a remedy as strychnia, or even some of the opiates, because they are capable of doing harm. Used in proper doses, and under proper circumstances, they all do a great deal of good.

DR. HILL, Milwaukee—That alcohol is, as it has lately been called, a narcotic, I think Professor Wood, in his vast work, has outlined it sufficiently well that we may understand it; a difference of opinion regarding the physiologic action of this drug, as in many others, being due to a difference between its influence when used as a therapeutic agent and as a toxic agent. Investigations which have led to the view that it is a narcotic or a soporific have been based on its use in almost lethal doses, and not in therapeutic doses.

There is another law in therapeutics which should be borne in mind in this connection, that any remedy which stimulates any nervous center will by its continued or excessive use produce paralysis of the same center. With these two suggestions in mind, I think we can readily reconcile the statements of those who consider alcohol a stimulant with those who consider it a paralyzer or narcotic. I think this drug, as clinical observation of many years has proved, is a most valuable stimulant, because when used in toxic doses it does produce other effects, constitutes no reason why he should cease employing it as a stimulant. Of course it has other effects; it has toxic effects; it has other effects in sepsis. Its dosage can not be given in drams nor in grams, for it is one of the remedies upon whose use the disease and the immediate condition of the patient have a wonderfully modifying influence.

DR. GROSVENOR—My chief object has been to show that experiments have been made which, to my mind, prove conclusively that upon the organs of special sense alcohol in these very small doses produces paralysis. By small doses I mean from half a dram to two dram doses. I am open to conviction if there is a scientific basis on which to prove that alcohol is a stimulant. Just because alcohol has, by our forefathers and great forefathers, been regarded as a stimulant, is no reason why we should regard it as a stimulant to-day. We are living in a new generation, and this subject of the action of alcohol on the human system has been revolutionized by men who are competent to experiment upon it and to carefully note the results.

SOCIETY PROCEEDINGS.

American Neurological Association.

Annual Meeting held at Philadelphia June 3, 4, 5, 1896.

The President, DR. F. X. DERGUM in the chair.

THE PRESIDENT delivered an address entitled

THE FUNCTIONS OF THE NEURON.

He dwelt at great length upon the various views advanced by Nansen and quoted several abstracts from this well-known author's work. Speaking of naked axis-cylinders, Dr. Dergum stated that they are in all likelihood a physiologic impossibility in the cerebrum: for were they numerous, we can suppose nothing but a constant overflow of stimuli from one cell to another, and consequent incoördination, not only of thought but also of action. This is the view advanced by Nansen. The speaker stated that the question had arisen in his mind as to whether the neuron was not an absolutely fixed morphologic element, and whether it did not possess a certain, though perhaps limited, power of movement. Continuing, he said: "Realizing the practical value and the wide application of this idea, I have examined the literature to see whether a similar interpretation of nervous phenomena has occurred to others, and to gather such facts, if any, as could be brought forward in its support. I found that this thought had occurred independently to three observers, one in Germany and two in France." Ramon Cajal, however, opposes the theory of the mobility of the neuron, and maintains, on the other hand, that the neuroglia cells possess a great deal of mobility. He points out for instance that the neuroglia cells of the cortex are at times stellate and at others much elongated. Their processes have numerous short arborescent and plumed collaterals.

Two phases can be observed in them, first a state of contraction, in which the cell body becomes augmented, while the processes become shortened and the secondary branches disappear, and secondly a state of relaxation, during which the processes of the neuroglia cells are again elongated. Ramon Cajal further maintains that the processes of the neuroglia cells in reality represent an insulating or non-conducting material, and that during the period of relaxation they penetrate between the arborizations of the nerve cells and their protoplasmic processes and render difficult or impossible the passage of nerve currents. On the other hand, when the processes of neuroglia cells are retracted, the various nerve cell processes which they formerly separated from each other are now permitted to come into contact. To me it seems as though Ramon Cajal admits the very thing against which he contends. Turning our attention for the moment to the subject of hysteria, we will see what a flood of light may be cast upon this hitherto so obscure and mysterious subject. Take the simple example of an hysterical paralysis and see how easily it may be explained. The neurons of a certain area of the cortex, for instance, retract the terminal branches of the neuraxis to such an extent that the latter are no longer in contact, or sufficiently near to the neurons in the spinal cord which supply the muscles of the paralyzed parts. When power is suddenly reestablished in hysterically palsied limbs, it simply means that the terminal branches of the cortical neuraxes, previously retracted, are again extended so as to reestablish the proper relations with the spinal neurons. It would be interesting indeed to follow out the ideas here brought forward in their application to the various phenomena presented by hysteria. Turning to hypnotism, we can see what a ready explanation it affords for the phenomena presented, and leaving this field entirely, we can see what an enormous value this interpretation of cortical action is for normal mental phenomena, taking for example the familiar instance of sleep. Numerous other ideas also suggest themselves in relation with the view here advanced, but time will not permit of my further discussing it.

DR. JAMES PUTNAM, of Boston, read a paper on

HEMORRHAGIC ENCEPHALITIS.

The author first referred to the literature of the disease. The principal symptoms of which are, 1, those described by Wernicke as due to hemorrhagic softening occasionally confined to the neighborhood of the third ventricle; 2, those described by Streumpell and others as attending more diffuse lesion of the hemispheres; 3, those connected with hemiplegia in children, which may be due to a similar lesion involving the cortex, as Streumpell formerly suggested. Osler has reported a number of cases showing that however grave the symptoms of this disease the outcome may be favorable. The author's case was that of a young boy who was attacked, two weeks after being ill with mumps, with paralysis of motion, of both eyes, deafness, coma and double optic neuritis. At the end of three months, however, he had recovered except for slight double vision and impairment of hearing. Ever since the illness he has been suffering from epileptiform attacks of short duration, but these attacks are gradually becoming less frequent. Reference was made to another case reported by the reader in 1892, where beside other serious cerebral symptoms, including double optic neuritis, temporary loss of hearing had also occurred. The cases reported by Osler were given in outline and the interesting fact noted that the cases referred to were like the one mentioned by Dr. Putnam, in children.

DR. L. C. GRAY said he would like to know if there was any retraction of the head in the case reported. His reason for asking was that some years ago he procured a book which gave an excellent description of what is now called hemorrhagic encephalitis and the remarks therein impressed him very much. He stated that he saw during his first ten years of practice four or five cases, all of which terminated fatally. In many cases the diagnosis is difficult and the prognosis is unfavorable even when the cases have seemed to run such a subacute course that you might think they would get well. Many cases are not susceptible to diagnosis except at the autopsy.

DR. B. SACHS said that the recognition of this form of encephalitis constituted a distinct advance in neurology. During the past year or two he had seen four cases, two in private practice which had terminated fatally and two hospital cases which recovered. One of the cases was hard to diagnose as to whether it was meningitis or encephalitis, but the one point on which he decided the case was that there was no tendency to coma. Encephalitis is a milder disease than meningitis, but the symptoms will vary very much. One of the cases seen by Dr. Sachs was interesting for the reason that the cerebral symptoms appeared the same day with the fever, the

former lasting for four days. In the speaker's opinion many cases have doubtless been reported as meningitis which were really cases of encephalitis.

DR. PUTNAM said that the prognosis in these cases was often very difficult to decide, and this view had been expressed by Oppenheimer. Fürbringer had mentioned that meningitis may be present with the encephalitis, in which case the differentiation would be difficult. Although some of the most violent cases have recovered, yet the repeated occurrence of coma is an unfavorable sign. If meningitis is present, bacteria will probably be there and the system will be flooded with the toxins and a great deal depends on how much poison is absorbed. The significance of retraction of the head probably is not known. He referred to a case of influenza in an elderly person who subsequently presented the symptoms of Jacksonian epilepsy on one side and he died at the end of the third day. Microscopically no lesion could be discovered, but the brain was edematous and here and there were areas stained yellow.

Abstract of paper by Drs. Jas. H. Lloyd and Joseph Sailer on a

CASE OF RAPIDLY FATAL CEREBRITIS RESEMBLING CEREBRO-SPINAL MENINGITIS.

The writers called attention to the fact that fulminating cases of the infectious diseases such as smallpox, scarlatina, measles, typhoid fever and spotted fever occur in which the diagnosis is exceedingly obscure and the disease is usually quickly fatal. These cases as a rule have their most marked symptoms in the nervous system. There is delirium passing into coma with depressed cardiac and respiratory centers, with high fever, and in the cases of the exanthema, often a purpuric or hemorrhagic eruption not always characteristic. These cases demand especially two things, first the determination of the exact effects upon the nervous system, and second, the determination of the microbe or toxic agent at work in any given case. The writers could only attempt the former study as the paper was not intended to deal with the bacteriology of the subject. The patient was a man aged 24 years who was taken suddenly with a chill followed by fever and intense cephalalgia and radialis. The patient passed rapidly into a condition of delirium merging into coma. Third nerve paralysis supervened, and on the third day a copious purpuric eruption appeared. This eruption presented ecchymosis and on the hands lesions like erythema nodosum. Blood and pus were found in the urine and vomiting of blood occurred before death. The patient died on the sixth day. The autopsy revealed disseminated local lesions in the cerebrum, mid-brain, pons and post-oblongata. Some migrated leukocytes in the perivascular spaces, little involvement of the membrane and a diffused nephritis. From extensive microscopic research the writers were able to report a disseminated local cerebritis. The infection had invaded the brain by way of the connective tissue structures, blood vessels, etc., and the nerve tissues proper were invaded secondarily. From the clinical standpoint the case probably comes under the head of "spotted fever."

DR. OSLER regretted that there was not more detailed reference to the condition of the kidney and referred to the readiness with which the diagnosis in these cases may be made. He stated that only last year, had it not been for the correction of his former impression, he would certainly have made a diagnosis of cerebro-spinal meningitis in a case of typhoid fever.

DR. J. J. PUTNAM stated that we may get the symptoms without the meningitis, it is certainly an addition to our clinical knowledge. To reinforce this fact may be mentioned that in diphtheria, although the characteristic symptoms had been present, some of the most recent observers had failed to find any lesion.

PROF. B. G. WILDER, of Cornell University, read a paper on THE ECTAL RELATIONS OF THE RIGHT AND LEFT PARIETAL AND PAROCCIPITAL FISSURES.

The parietal and paroccipital fissures may be either completely separated by an isthmus, or apparently continuous. When so continuous ectally there may still be an ental and concealed vadum or shallow. Disregarding the vadum on the present occasion, the ectal relations of the two fissures may be designated as either continuity or separation. That continuity occurs more frequently on the left side, has been noted by Ecker, Cunningham and the writer. Hitherto, however, statistics have included unpaired hemispheres as well as mates from the same individual. The following statement is based upon the cerebrums of fifty-eight adults of both sexes and various nationalities and characters. The speaker has examined forty-eight; the other ten have been accurately recorded

by Bischoff, Dana, Jensen and Mills. The four possible combinations of right and left continuity and separation occurred as follows:

1, left continuity and right separation in twenty-seven, 46.5 per cent.; 2, right and left continuity in twenty-two, 38 per cent.; 3, right and left separation in eight, 13.8 per cent.; 4, left separation and right continuity in one, 1.7 per cent. When five groups are recognized the combinations are as follows: A. In eight moral and educated persons, combination 1, 62.5; 2, 25; 3, 12.5; B. In twenty-three ignorant or unknown, combination 1, 56.5; 2, 34.8; 3, 8.7. C. In twenty insane, combination 1, 40; 2, 35; 3, 20; 4, 5. D. In four murderers, combination 1, 0; 2, 75; 3, 25. E. In three negroes, combination 1, 33; 2, 67. So far as these fifty-eight individuals are concerned, the most common combination, viz, left continuity and right separation, is decidedly the rule with the moral and educated, less frequent with the ignorant and unknown, the insane and negroes, and does not occur at all in the murderers. The only instance of the reverse combination (left separation and right continuity) is an insane Swiss woman. The only two known to be left-handed presented the more frequent combination 1.

These statistics suggest many especial queries and problems, some of which were briefly indicated. But the speaker wished this to be regarded as a preliminary communication, and asked the coöperation of other members in the effort to obtain satisfactory records of larger numbers, particularly of brains of well-born, moral and educated persons. For this purpose a blank form was outlined.

DR. THEO. DILLER, of Pittsburg, read a paper on

A CASE OF PROGRESSIVE MUSCULAR ATROPHY OF SUDDEN ONSET.

He related the details of a case which came under his observation three years ago, and stated that the sudden onset of palsy followed by atrophy and the absence of sensory phenomena led him to diagnose the case as one of poliomyelitis adultorum. The beginning of the patient's trouble was in an ophthalmoplegia. After an absence of two years the man again came under the speaker's care, when the atrophy and loss of power in the muscles had markedly increased. The biceps, triceps, scapular and ulnar groups had become involved and the finer movements of the fingers were lost, as was also the power of supination. At this time the patient was unable to put on or take off his clothing unaided. There was marked decrease in the response both to galvanism and faradism in the paralyzed muscles. Dr. Diller considered the case could be fairly regarded as one of progressive muscular atrophy, for the progressive feature was for two years the most important feature of the case. Ophthalmoplegia as a symptom of progressive muscular atrophy must be rare, for but scant references are made to it in literature. Strychnin had a very marked effect in staying the progress of the disease.

DR. WM. BROWNING, of Brooklyn, read a paper on

PITTING ABOUT THE HAIR CUPS: ATROPHIC CHANGE IN THE SKIN IN CERTAIN NERVOUS DISORDERS OF CENTRAL ORIGIN.

The author described a presumably hitherto unrecognized alteration in the skin. From seven or eight observations of such cases, he was able to give the limits of its recurrence. So far it has been seen only in progressive muscular atrophy of spinal origin, or any cases complicated with atrophy evidently due to cortical disease. In other affections attended by atrophy, such as infantile spinal paralysis, neuritis, pseudo-hypertrophy, etc., it has not been found. It is hoped that it may prove a useful help in differential diagnosis, especially between the forms due to peripheral and central disease. The change consists of an areola-like faint depression, frequently oval in the direction of the lines of the skin, though it may be irregular or circular in form about the exit of each hair. Usually the depression is a trifle paler than the surrounding skin, resembling, but not really being, a minute scar. It is not observed especially in hairy regions, like the scalp, but only over the seat of muscular atrophy, notably on the leg and thigh, although also on the upper extremity. All the cases reported had reached or passed middle life.

A CASE OF SYRINGOMYELIA, LIMITED TO ONE POSTERIOR HORN IN THE CERVICAL REGION, WITH ARTHROPATHY OF THE SHOULDER JOINT AND ASCENDING DEGENERATION IN THE PYRAMIDAL TRACTS.

By Drs. F. X. DERCUM, Philadelphia, and Wm. G. SPILLER, Philadelphia.

Three years after a strain of the back the patient began to suffer from pains in the legs, a band-like pain about the lower part of the chest, weakness in the lower limbs and a spastic gait. Complete paraplegia with contractions, more marked on the right side, wasting of the lower limbs, paralysis of bladder

and rectum developed later. Cutaneous sensibility was lost in the legs and upon the trunk as high as the nipple on the right side and a little above the umbilicus on the left. The sense of temperature was absolutely lost over the right arm, the right shoulder and the right side of the neck, and also upon the adjacent portions of the right side of the trunk above the nipple line. There was some analgesia of the right arm.

The right shoulder joint began to swell, and from rupture of the capsular ligament cellulitis with redness and local heat was produced, but with little or no pain. In extension the humerus assumed the position of a subglenoid luxation. Death was caused by exhaustion. At the autopsy the capsule of the right shoulder joint was found much thickened and roughened on the inner surface. The head of the humerus had disappeared, the bone having been eroded to some little distance below the surgical neck. A cystic tumor was found in the axilla, containing a friable fatty material. The surface of the glenoid cavity was much eroded, roughened and porous; it was abnormally large, and extensive bony deposit had taken place along its edges. The coracoid process exhibited a thick and firm accretion around its entire edge. Sections were made in the Pepper Laboratory from the level of nearly every spinal root and from many spinal ganglia.

By the microscopic examination degeneration was found of the crossed pyramidal tract as high as the substantia reticularis of the second cervical segment and of the direct pyramidal tract as high as the motor decussation upon the right side, and for a short distance of the crossed pyramidal upon the left. This was believed to be ascending on account of the following facts: 1, absence of any microscopic lesion above the medulla oblongata; 2, degeneration of the crossed and direct pyramidal tracts on the same side of the cervical cord, intense in the lower cervical region near the lesion and diminishing gradually in intensity in the cervical segments and finally becoming very indistinct in the upper cervical region; 3, absence of all degeneration in the anterior pyramids; 4, long duration of a chronic process.

While certain associative fibers may be considered degenerated in these columns, the entire antero-lateral column contains such fibers and the degeneration was notably in the area occupied by the crossed and the direct pyramidal tract. This ascending sclerosis is probably in greater part due to destruction of motor fibers deprived of their function.

Degeneration of the direct cerebellar tracts and of the tracts of Gowers was traced as far as the inferior peduncle of the cerebellum. Intense pachymeningitis was noticed from the second lumbar segment to the exit of the third dorsal roots. The arthropathy of the right shoulder was not due to any special changes in the cord or spinal ganglia. The posterior roots were not affected even where the pachymeningitis was most intense; the anterior at one part of the dorsal cord were degenerated. In the entire cervical region as high as the second cervical segment the cavity was limited to the right posterior horn. The gliosis extended from the extreme end of the conus terminalis to the second cervical segment. The microscopic examination explained satisfactorily the symptoms observed in life.

DR. HENRY S. UPSON asked if the degeneration was in the lateral column. In his opinion the degeneration might be susceptible of examination in two ways, first, that the short fibers might be effected by a lesion, and, second, that the degeneration might be in consequence of or merely coincident with the syringomyelia. The particular point is whether this can be made out to be an ascending degeneration.

DR. JAMES HENRIE LLOYD referred to the ease with which a diagnosis of syringomyelia can now be made. He referred to a case reported by himself in 1892 in which there was distinct arthropathy of the left ankle joint and there was also some ascending degeneration of the lateral tract.

DR. B. SACHS referred to the great variability in the symptoms if the cases are watched for a considerable length of time and stated that during the further course of the disease a number of the sensory symptoms will disappear, so that sometimes cases of syringomyelia will exist in which there is almost complete cessation of sensory function.

DR. M. A. STARR—Although admitting the ease of diagnosis, he gave the details of a case under his own observation in which he was undecided whether the patient was suffering from syringomyelia or hysteria. Judging from the objective symptoms he thought she had syringomyelia, but other than that it seemed to be a clear case of hysteria.

DR. J. J. PUTNAM referred to an interesting case of syringomyelia in which the disease began in the dorsal region. The patient's condition was much improved by an operation performed by Dr. Keen at the request of Dr. Putnam under the impression that there might be a tumor under the cord. The

cord was found enlarged and discolored as though it had been the seat of a tumor, but no tumor was found. He referred to the difficulty often experienced in diagnosing the disease in children.

DR. HUGH T. PATRICK observed that the direct cerebellar tract was not traced as high as the pons and said he thought it would give a false inference if it was not mentioned, that it extended this high. Personally, he traced it to the corpora quadrigemina. He referred to a case of this disease which had gone the rounds of London hospitals for years as a case of hysteria. He also stated that the French have called attention to the fact that syringomyelia and hysteria are particularly liable to be combined and they have also described acromegaly combined with syringomyelia.

DR. SPILLER stated that the degeneration was distinctly marked in the direct and crossed pyramidal tracts. The degeneration was the most extreme near the lesion and decreased gradually in ascending so that at the upper part of the cervical region it could hardly be found. As to the loss of tactile sense the symptoms vary according to the parts destroyed. If the posterior columns are destroyed, the tactile sense must be destroyed also.

(To be continued.)

Medical Society of the State of Delaware.

One Hundred and Seventh Annual Meeting held in Newark, June 9, 1896.

The President, DR. JAMES T. MASSEY, occupied the chair and there were about fifty members present.

DR. H. G. M. KOLLOCK made the address of welcome and called the attention of those present to the many important discoveries of medical interest during the past year. He made special reference to the Röntgen rays and said he hoped this would be but the beginning of a practical method to view all the organs of the body.

DR. A. T. NEALE read a paper entitled:

CONTAGIOUS DISEASES OF THE LOWER ANIMALS AND THEIR RELATION TO THE HUMAN FAMILY.

The author called attention to the fact that under the revised code of the Delaware laws the Governor has the power to proclaim an epidemic of disease among cattle, to forcibly take and kill live stock and take every precaution to protect the lives and property of the public without any recompense to the individual loser. Severe as this law appears to be, it is almost inoperative, for the live-stock owner quietly removes his dead, suppresses his suspicions, and an epidemic is established upon his own and the adjoining farms. If the present laws are practically inoperative, from their failure to recognize the rights of individual sufferers, if this State can legally acquire and circulate the information which makes the recognition of said interest possible, then it is clear that the present laws should be so amended as to give permission to the Governor to employ State funds in the interest of the individual, just as he is now empowered to use them in the employment of the sheriff for the protection from such epidemics.

DR. BLACK believed that about 20 per cent. of milk cows are tuberculous and that many of the summer complaints of children were due to this cause. He advocated the sterilization of milk and stated that it should be brought to the boiling point a second time.

DR. NEALE in closing stated that out of 1,000 cows examined in one year, 19 per cent. were found tuberculous.

DR. JAMES H. WILSON read a paper on

THE SOURCE AND CAUSE OF THE IRREGULAR FORM OF MALARIA.

The author stated that the term is synonymous with swamp or ague poison. Aitken speaks of paludal and of animal malarial poison and says that this toxic poison is capable of inducing certain morbid phenomena, known as intermittent and remittent fevers. Thayer and Hueston have reached the conclusion that the tertian type of fever depends on the presence of a parasite in the blood, which passes through its cycle of existence in about forty-eight hours. In regard to the estivo-autumnal fever, the same authors conclude that it is due to the organism described by Marchafava and Selly, but the existence of this parasite has not been followed out in a satisfactory manner. The main seats of infection are the spleen, bone marrow and internal organs. Dr. Wilson believes that the mode of infection of irregular forms of malaria are identical with those of the regular forms and that the admission into the system is similar. The typhoid malaria referred to by Dr. Woodward during the late Rebellion was typhoid fever complicated with malaria and this affection has been placed where it properly belongs by the clinical thermometer. The two factors necessary to the production of malaria are water insatura-

tion with protracted heat. The speaker narrated an instance which proved that the malarial parasite existed in drinking water both pure and impure.

DR. JUDSON DALAND, in discussing this paper, stated that while many cases, and probably the majority, are transferred to individuals through water, unquestionably many are carried through the atmosphere. Out of sixty or seventy cases studied by the speaker, 80 per cent. were of the ordinary variety. The speaker believed that many cases of malaria were instances of double infection, at the time the malarial intoxication was acquired another parasite was also taken.

DR. WM. C. PIERCE of Wilmington read a paper entitled

MALARIA WITH SPECIAL REFERENCE TO SOME OF ITS IRREGULAR FORMS.

The author spoke of the geographic distribution of malaria in the United States and Europe. He referred to the effect of the soil in producing malaria and stated that several species of the plasmodium may coexist and produce the varying types of the disease. He called attention to two cases of malaria which developed many years after they were supposed to have been cured and one case was especially interesting from the fact that it occurred five days after the termination of labor, the woman having had no malarial symptoms for some years previous.

DR. C. M. ELLIS referred to the fact that malarial poison passes through cycles the same as many other diseases. He demonstrated this by mentioning localities and time of the recurrence of malaria.

DR. JUDSON DALAND referred to the few cases in Pennsylvania as compared with the number seen in Maryland and surrounding country. It has been proved by Dr. Thomson of New York that typhoid may be complicated by malaria. Referring to the question of malarial cycles, Dr. Alfred Stille of Philadelphia formerly said the same thing at the time the malaria was prevalent along the Schuylkill River years ago.

DR. R. G. ELLEGOOD stated that many years ago when remittent fever was prevalent he had seen eight or nine persons suffering at the same time out of a family of fifteen. None of the cases presented any typhoid symptoms, but were typical cases of remittent malaria.

DR. R. B. HOPKINS read a paper entitled

THE TREATMENT OF MALARIA.

The author said in his opinion the reasons for this disease not being as prevalent as formerly are due to atmospheric changes, improved condition of the soil, better drainage and purer water supply.

DR. DALAND in referring to the diagnosis of malaria stated that the one pathognomonic sign of this disease was the existence of the malarial parasite. It lives forty-eight hours and during this time completely changes its appearance. It will enter a red blood cell, feed upon the contents and increase in size at the expense of the stroma. Nothing resembles this appearance in health or disease and the diagnosis of malaria is complete so soon as this parasite is discovered. Dr. Daland then referred to the theory that the rupture and disintegration of this body in the blood is coincident with the occurrence of the chill.

DR. MARSHALL reported a

CASE OF PERNICIOUS ANEMIA.

In this instance the diagnosis was difficult to determine between leucemia, Addison's disease and pernicious anemia. The patient was a bank teller, 33 years of age, who had a pulse of 120 and a temperature of 102 degrees when Dr. Marshall was called. The blood count at this time showed 1 white to 235 red, the red then numbering about 1,300,000. The diagnosis of pernicious anemia being thus confirmed, the patient was placed upon red bone marrow and arsenic and in a few weeks the red blood corpuscles numbered 2,500,000. In two weeks the count showed 3,500,000, and two weeks later 3,800,000. Three months afterward the count showed 4,400,000. The man continued to improve and is now back attending to his duties in the bank.

DR. C. M. ELLIS read a paper entitled

OBSTETRICAL COMPLICATIONS.

The author called special attention to the great danger of the convulsions of pregnancy before term. His experience included eight cases, occurring at different stages of pregnancy and showed clearly that when a convulsion occurs before term, unless it is of systemic origin, immediate delivery is imperative, without regard to the presence or absence of uterine contractions or the condition of the os as to dilatation. If the convulsion begins early, the uterus should be emptied by the most expeditious method and all medicinal treatment should be secondary to this one great object. This is necessary for the reason that the percentage of fatality from eclampsia is fully

50 per cent. This high death rate is greatly exceeded when the delivery is not accomplished or if it is delayed until several convulsions have occurred or until uterine contraction and dilatation have supervened. Of the eight cases seen by the author, five died and three recovered. Of the five that died premature delivery was effected, one on the sixth day after the initial convulsion, one forty-eight hours after, one eighteen hours after the first convulsion, three others having followed and the patient being moribund at the time and one lay in convulsion three days without any attempt at delivery. The experience gained from these eight cases would certainly justify premature delivery.

DR. ELLIS had never seen a death occur before delivery after the operation had been initiated and he believed the uterus should be evacuated immediately after the first convulsion. When albumin appears in the urine the more imminent is the danger of eclampsia and if this accident is threatened, it may be necessary for the attending physician to hasten delivery without waiting for the convulsive seizure. The speaker denounced the indiscriminate use of morphia hypodermatically in cases like these.

DR. GEO. M. BOYD of Philadelphia—As to the treatment from a medicinal standpoint, he recommended chloral by the rectum. He believes the mortality depends largely on the kidney lesion, as many cases of eclampsia during labor are the result of interstitial nephritis before pregnancy.

DR. P. W. TOMLINSON of Wilmington, mentioned a case in which twenty-four ounces of blood were drawn and decided improvement followed.

DR. E. S. DWIGHT read a paper entitled

CARDIAC DISEASES AS ENCOUNTERED IN CENTRAL DELAWARE.

He said that frequently commencing heart lesions were evidently due to the absorption of some morbid product through the abraded service of the bladder. He believed the ulcerative endocarditis had been the cause of death in one of his cases of eclampsia and he is of the opinion that where ulcerative endocarditis can be recognized before embolism has occurred, it is important that the patient should be kept in a recumbent position and as quiet as possible.

DR. H. J. STUBBS of Wilmington read a paper entitled "Three Cases of Appendicitis, one of Unusual and Fatal Complication," in which he related the details of the three cases and stated that a pin had been found in the appendix of one of the cases. He strongly recommends prompt medical and surgical treatment.

WM. P. ORR of Lewes was elected president; WILLARD SPRINGER of Wilmington, vice-president; P. W. TOMLINSON of Wilmington, secretary; and WM. C. PIERCE of Wilmington, treasurer for the ensuing year.

The society adjourned to meet in Rehoboth in June 1897.

Medical Society of the State of Pennsylvania.

Forty sixth annual Session of the Medical Society of the State of Pennsylvania, held at Harrisburg, May 19 to 21, 1896.

(Concluded from page 1227.)

At the afternoon session Dr. Judson Daland of Philadelphia, read a paper illustrated with lantern slides, "Certain Forms of the Malarial Parasites."

DR. L. J. LAUTENBACH of Philadelphia, read a paper,

PHONO- AND PNEUMO-MASSAGE FOR SUPPURATIVE DISEASE OF THE EAR.

In cases of middle ear suppuration there are three aspects from which the subject of the treatment must be studied. The first of these is the prevention of the inflammation; the second which is to some extent included in the first, is the subjection of the inflammatory condition and the healing of the diseased parts, while at the same time stopping the ear discharges; the third, is to some save the hearing or to restore it when impaired. I hope in this paper to so present the subject of massage as applied to suppuration cases, that you will be convinced that in connection with our older and well tried remedies, it is a valuable aid in treatment, but there is a sphere which it more thoroughly fills than any other remedy or remedies. In all cases of suppuration, acute or chronic, it is necessary to cleanse the ear as thoroughly as possible of all retained secretions. There is no doubt that if the middle ear cavity were kept constantly clean, the inflammatory condition would often subside very quickly. To remove these discharges, I use my pneumo massage instruments in connection with wet or dry cleansing. I first treat the ear according to the present methods and when I consider it fairly clean, I use an exhaust apparatus with a pressure of from 2 ounces to 4 pounds per square inch for from 3 to 10 minutes, employing about 300 exhausts per minute. Then I again thoroughly cleanse the ear with cotton

and if I am at all suspicious of there being more suppuration present, I again apply the exhaust pump. After thus cleansing the ear, I use drying and stimulating preparations in the usual manner. Often in simple cases after cleansing the ear, I lightly plug with cotton using no other treatment. Pneumo or suction massage thus applied fulfills in part all three of the treatment indications, preventing the extension of the disease, favoring the subsidence of the inflammation and improving or saving the hearing. It accomplishes these three indications by the complete cleansing occasioned and in addition, the last of these by the thorough kneading movements produced in the conducting apparatus, preventing loss of functional activity and relieving pressure on the internal ear. We can by means of suction massage thoroughly applied (often and sufficiently long) break up these ankyloses, stretch and cause absorption of the bands, break the adhesions and often reduce the thickenings and growths of the mucous tissues and heal the ulcerations. By bringing about these results we succeed in restoring to the conducting apparatus its normal function. During this process we usually succeed at the same time in relieving the abnormal pressure on the internal ear. By the use of phonomassage we can, as elsewhere pointed out, stimulate the auditory nerve ends to renewed activity. I no longer tell my patients that as the discharge ceases the hearing will probably grow worse. I no longer find it to be so. I find the hearing almost invariably to improve as the treatment progresses. Of course, under the old method the hearing often did grow worse; no effort being made to prevent the organization of the exuded lymph; there was an entire lack of any treatment employed to overcome the bad effects of the abnormal healing processes; the ossicles became ankylosed, and adherent to adjacent structures; the drum head formed attachments; nothing was done to prevent the stapes being jammed into the oval window; no steps were taken to prevent adhesions, nor was it considered necessary in any way to normally stimulate quiescent auditory nerve endings. In fact, all that was done to soothe, cleanse and heal the ear was perhaps the occasional use of the Politzer inflation. My method provides for the relief of all these conditions and by a rational common sense treatment endeavors to overcome all, and I am satisfied that it does so measurably well, as my results to-day are infinitely better than before its introduction. The results both as concerns the cure of the suppuration, the length of time required therefor, as well as in the degree in which I succeed in restoring the hearing being conclusive proofs in this direction.

My conclusions are briefly as follows: Pneumo-massage aids in the prevention of extension of inflammation as well as in the subsidence of the inflammatory action through the aid it affords by thoroughly cleansing the middle ear of all the discharges, thus relieving the excessive tension, thus preventing infiltration and disintegration of ear structures with consequent extension to the internal ear or mastoid cells or both. Pneumo-massage preserves intact the normal sound conducting structures and restores them when ankylosed or abnormally attached or when restricted in their movements to a condition more nearly natural than can be attained by any other method. Pneumo-massage relieves the increased pressure on the internal ear so often observed as the cause of deafness in these cases. Phono-massage restores, at least in part, to the internal ear structures their normal receptiveness by occasioning a physiologic stimulation of the nerve endings and their connecting parts which had either from disuse or increased pressure been placed in a dormant or non-responsive condition.

DR. E. W. HOLMES of Philadelphia, read a paper, "Cerebral Concussion and Compression," with a report of a case trephined.

DR. ERNEST LAPLACE of Philadelphia, read a paper on "Surgical Treatment of Insanity," with a report of cases. Both these papers showed good results from the operative procedure.

The committee on the Jefferson Medical College Hospital reported that they had learned that the advertisement had been published without the knowledge of the gentlemen whose names appear and it was their belief that the matter having now come to their notice would be so arranged by them as to fully comply with the Code of Ethics. The committee deprecated the action of persons who by having copies of the advertisement printed and distributed in the hall of this Society had made it appear to have more the interest of the individual than the welfare of the Society. The report gave much satisfaction and was adopted with few dissenting voices.

DR. A. O. J. KELLY of Philadelphia, read a paper,

THE SIGNIFICANCE OF MURMURS IN THE DIAGNOSIS OF VALVULAR DISEASE OF THE HEART.

The study of the exact significance of murmurs in the diagno-

sis of valvular disease of the heart may not inappropriately be prosecuted by arranging our cardiac cases into three distinct classes: 1, cases in which the presence of a murmur assists in the diagnosis of some valvular lesion; 2, cases in which, despite the presence of a murmur, valvular disease may not be diagnosed; 3, cases in which valvular disease may be diagnosed without the detection of any murmur whatever. The actuating motive of the communication is therefore that a murmur alone, that is, without corroborative evidence, is never diagnostic of any valvular lesion of the heart. We must always precede our examination of the heart by a thorough physical examination of the lungs and pleurae. Considering murmurs we must determine the murmur to be of endocardial origin, eliminating all question of exocardial genesis. The so-called mitral systolic murmur at the apex is usually considered diagnostic of mitral incompetency. But a similar murmur in the same area may be due to anemia, or be of cardio-pulmonary origin. And the murmur of mitral insufficiency may be heard with greatest intensity up toward the pulmonary cartilage. The organic murmur, as well as the inorganic, is subject to postural influences and in certain conditions may be absent. The apical diastolic or presystolic murmur of mitral stenosis is neither as strictly localized to the apex, nor as pathognomonic of the condition as is generally supposed. A presystolic murmur at the apex may not only be due to a mitral stenosis, but may likewise owe its origin to an aortic incompetency or an adherent pericardium. A mitral stenosis may frequently be diagnosed without the detection of any murmur whatever, especially when there is heard a reduplication of the second sound at the apex and not at the base of the heart. Exercise care in the diagnosis of single lesions at the mitral orifice, they are of rather infrequent occurrence. The aortic diastolic murmur of aortic insufficiency may be mistaken for a transmitted bruit from the veins of the neck, and may often be absent, or if present be accompanied by an aortic systolic murmur without there being present any aortic stenosis whatever. An aortic systolic murmur is not diagnostic of aortic stenosis. In making a diagnosis of any valvular lesion we must demonstrate the physical signs other than the murmur which attend upon the lesion; hypertrophy and dilatation, accentuation or absence of the normal heart sounds at the apex and base, pulse, examination of the veins, auscultation of the arteries, etc. This pertains to valvular disease of the right as well as of the left side of the heart. Because of the complexity of the conditions in cases of combined valvular disease the diagnosis is more difficult, but is based upon similar principles. It is not the character of a murmur, nor its area of distribution, nor its direction of transmission, that determine its value in the diagnosis of valvular disease. These are subordinate to the time of its occurrence and the site of its production. Murmurs are usually present in cases of cardiac valvular disease, so also is albumin present in the urine in the event of nephritis, but neither is pathognomonic of the condition which they attend, they both require confirmatory evidence. We must devote more attention than is usually accorded to the other and important physical signs of valvular disease of the heart. The murmur is but one element in the diagnosis, the least important.

DR. W. T. ENGLISH of Pittsburg, read a paper,

THE ABUSE OF DIGITALIS.

A vague idea exists that this drug is a cure for heart disease, hence the abuse in its employment. Much variation exists as to the dosage owing to the variety of forms, now the tincture, now the infusion, the powdered leaf, etc. The tincture should be employed for its tonic effect. The infusion is a diuretic. Both may be combined. The objection to the leaves is that they are not readily assimilated. It is employed indiscriminately as a diuretic in Bright's disease. It is often forgotten that its effects are slow in coming as well as deliberate in leaving. It is fool-hardy to use it in chronic nephritis accompanied with high peripheral pressure. It is forgotten that in moderate doses it stimulates the musculo-motor portion of the heart, increases the action of the inhibitory apparatus, etc. In those whose vocation forces them to the extreme of exertion, the heart becomes muscular in proportion. Such use of digitalis is a sin against the heart, a goad to a loaded organ. In palpitation due to neurosis conditions its use may convert it into an incurable disease. One fault is to give it without telling the patient to abstain from exercise while under its influence. Such persons should live in perfect physical and mental quiet. In malformation it is contraindicated. In mitral regurgitation there is a time when it is valuable.

DR. W. REBER of Pottsville, read a paper,

THE CORRELATION BETWEEN THE IRIS AND THE PATELLAR REFLEX TENDON.

He considered the frequency of association of the iris and

the patellar tendon reflex, especially in tabes. It will reflect the different views as to the nature of the true primary lesion in tabes, thereby also considering the lesion that brings about joint and frequently coincident involvement of both these reflexes. In this way we hope to show that the original change is a vascular one, setting up a starvation process in consequence of which the cerebro-spinal activity is obtunded (a condition not infrequently observed in tabes), and abolition of the iris and patellar reflex naturally follows.

The President then thanked the Society for the many courtesies which had been accorded him while in the chair and appointed Drs. McCandless and Detwiler to escort the President elect to the platform.

DR. E. E. MONTGOMERY of Philadelphia, then assumed the chair as President and thanked the members for the honor done him in this election.

DR. B. A. RANDALL of Philadelphia, read a paper,

SIMPLE AND EFFICIENT TREATMENT OF CHRONIC CATARRHAL DEAFNESS.

These cases are the reproach of aural surgery. To many, ear diseases appear an unknown and unknowable land. These are one-third of the surgeon's work. In the majority decided gain will follow rational treatment, no elaborate apparatus is needed. The naso-pharynx from which the affection proceeds must be gotten into better condition. Vigorous spraying with an alkalin fluid as Dobell's in the hand, atomizer cleanses the vault, then mopping the region of the mouth tubes, etc., with the bent applicator charged with glycerole of tannin or of iodine. An oil spray can follow with advantage, say menthol-camphor 1 to 2 per cent. This gives a protecting coating to denuded surfaces and medicates the cavities with a stimulating disinfecting vapor and lubricates the nose for the easy passage of the catheter. Massage with the pneumatic speculum should complete the process. The possibilities of harm are at a minimum and a year will show decided benefit. Often patients with a record of no benefit, have gone ahead most flatteringly under this and he had found old cases of his own give evidence of its potency.

All the papers, of which there were quite a number which had been omitted for want of time, were on motion declared as read by title and referred to the committee of publication. Votes of thanks were adopted to all who had aided in making the meeting so enjoyable. A motion was adopted for a committee to report as to the advisability of meeting every 2nd or 3d year at Pittsburg, Philadelphia or Harrisburg and to found a museum and library for the State Society. The History of the Society ordered to be prepared last year by the secretary was called for and the secretary announced that it would be ready and be printed with the Transactions. The State Board of Medical Examiners asked permission to print its report of those licensed in the Transactions. Granted.

The President appointed to prepare the addresses for next year: On Medicine, Dr. W. E. Hughes, Philadelphia; on Surgery, Dr. J. Chalmers DaCosta, Philadelphia; on Obstetrics, Dr. J. M. Baldy, Philadelphia; on Hygiene, Dr. A. P. Brubaker, Philadelphia.

The Society then adjourned to meet in Pittsburg, third Tuesday in May, 1897.

Kentucky State Medical Society.

(Concluded from page 1232.)

Forty-first Annual Meeting, held at Lebanon, June 10-12, 1896.

FIRST DAY—EVENING SESSION.

The President, DR. JOHN A. LEWIS of Georgetown, delivered the President's annual address. He referred feelingly to the honor conferred upon him by his election to the presidency by his confrères, and extended a warm welcome to the brilliant audience assembled. He stated that while casting about for a subject for discussion he happened to read of that old-fashioned doctor in Bonnie Briar Bush, by Ion Maclaren, and he chose the "Prolongation of Human Life." Life must surely be lengthened by the right way of living. Three questions are to be propounded: 1. Is it desirable to prolong life? The "mugwumps" of life pity that class who answers, "No," to this question. Accompanied by decrepitude prolonged life would not be desirable. A most potent reason for desiring prolonged life is wisdom. William E. Gladstone is the best living example of this reason. When he speaks the world hears and profits. Emperor William I. of Germany, a magnificent personage, unified Germany by wisdom and arms and lived 91 years. Robert Louis Stevenson, the gifted fiction writer, whose young life went out in Samoa where he went for life, was glad to live for the living. A mind of treasure was lost with the

death of Pasteur. Whatever is true of all these may be true of everyone no matter how humble. Why is life so short? What a vast difference between the limit of Moses' time and our three score years and ten! We are violators of laws of health in ten thousand different ways. What part has disease played in shortening life? It is not sent by divine source to harass mankind. Nearly all are caused by man's own violation of laws. Specific diseases sprung from long existing unhygienic surroundings, and man is largely responsible for existence of disease. How far is heredity responsible for disease existing? Robust health is transmissible from father to son; on the other hand the tendency to tuberculosis, etc., being transmissible, is indisputable. Scarcely one of us can boast a clean bill of health and this is due to heredity alone. This can and should be prevented. It is beyond law, but not public opinion. Heredity should be talked of from pulpit and in the home; the iniquities of transmission to three and four generations. Can any agencies lengthen life? Man can do everything to prevent disease. Cleanliness surely is next to godliness. Pure air and water, employment and reaction, rest and exercise, are all essentials. Dead must be cremated, dwellings properly ventilated; people will live longer out of doors than in crowded dwellings. There is no health without pure water; it should be filtered. Live abstemiously. Man is a reckless eater; 80 per cent. eat twice as much as required to live. Whisky and tobacco are both to go. Our habits of life must be modified till men do not wear their lives out trying to live. Gospel of long life should be heralded by every means possible; by press, pulpit and people. Physical culture and physiology should be recognized in all schools. Our State Board of Health has done great work for our State health. Gladstone said: "Medicine is the most progressive science in the world." Physicians must mold sentiment, as such and as philanthropists, but must demand in return the support and confidence of the people.

DR. J. B. MARVIN of Louisville, delivered an address upon
CONTAGIOUS AND INFECTIOUS DISEASES.

There has been a steady progress upward and onward. We know more of hygiene than formerly. This is a microbe age; people are sick about them. The vast majority of microbes are harmless; many are of the greatest good. The few that are harmful can be counted on the fingers; but they are very harmful. They are not bugs; far from it. The newspapers have ridiculed germs under this name. The laity are to be instructed by the doctor in regard to the life history of germs, and in turn are of great help to the doctor. Seed, soil and season are necessary for the growth of all germs, the sum and substance of the teaching of modern medicine. In speaking of consumption he described the organism, the seed and the soil. The ladies can inaugurate a reform in the iniquitous habit of spitting. Stop promiscuous kissing of children; be a great help to the doctor. Bring public opinion to bear upon carriers, steamboats and railroads. Become nose breathers, for the nose is a great filter. Typhoid fever is an eminently preventable disease; what a source of evil is an infected water supply. Not so much bad air, but bad water is very frequently responsible for malarial fever. Diphtheria is frequently a disease of neglect. Proper inspection of throats, breakage of slates, stoppage of common drinking cups in schools, Sunday schools and public places. The best disinfectant is fresh air and plenty of it, and likewise sunlight. Like sin these organisms like darkness and flourish there.

SECOND DAY—MORNING SESSION.

DR. HENRY E. TULEY introduced the following resolution: WHEREAS, Resolutions concerning vivisection were passed by the AMERICAN MEDICAL ASSOCIATION at Atlanta, therefore be it

Resolved, That the resolutions mentioned and published in the JOURNAL of the AMERICAN MEDICAL ASSOCIATION express the sentiments of the Kentucky State Medical Society and that our secretary be requested to send copies of these resolutions to the senators and representatives in Congress from our State. On seconding by Dr. J. A. Larrabee this was unanimously passed.

Delegates from the Kentucky State Pharmaceutical Society were received and invited to a seat on the platform.

A communication was read from the secretary of the Mississippi Valley Medical Association, inviting the members of the State Society to the meeting of this Society at St. Paul.

A communication was received from Surgeon General Sternberg requesting action by the State Society on vivisection covered by the resolution offered by Dr. Tuley.

Committees were appointed by the President on Necrology and upon Legislation to influence the legislature in behalf of the anti-abortion law.

A report was received from the committee appointed at the last meeting to "Collect and Codify" the Constitution and By-Laws of the Society. On ruling of the President, as the Committee had revised the Constitution contrary to the resolution by which the committee was appointed last year, the discussion was deferred one year.

DR. W. H. WATHEN of Louisville, opened the discussion on hysterectomy by reading a paper on

VAGINAL HYSTERECTOMY.

In support of this method the following reasons were offered: 1. There is less shock and more rapid and complete convalescence, the patients usually sitting up within a week and walking a few days later. 2. In pelvic suppuration there is less danger of septic infection from soiling the peritoneum. 3. Absence of suture or mural abscesses and of sinuses following the use of drainage or infected ligature. 4. Immunity from ventral hernia. 5. A lower mortality, fewer post operative complications, and a more complete restoration to health in a relatively greater number of cases.

DR. A. M. CARTLEDGE of Louisville, read a paper on the opposite operation,

SUPRA-PUBIC.

Each method has its indications and limitations. The most perfect operation is that which the most perfectly removes the pathological condition, other things being equal. If to leave diseased ovaries and fragments of pus tubes, or one ovary or the shell of a diseased uterus after the heart has been dug out or cut is perfect surgery, and surgery that will stand the test of time, then statistics of vaginal hysterectomy show better results than the abdominal method. The combined method in many cases is indispensable. Abdominal hysterectomy finds its only objection in the fact that it entails an incision through the abdominal wall. In myomatous tumors amputation is done at the cervix. If infection is present the entire organ is removed. Drainage by the vagina. In case of growths, the small button of cervix is cauterized and dilated from above and a small strip of gauze carried through to drain the dead space resting between the closed peritoneum above and the otherwise closed cervix below.

DR. LOUIS FRANK of Louisville, read a paper on

OPERATIVE PROCEDURES FOR PELVIC INFLAMMATION.

In all operative work aim must be to obtain the best results to the patient, sacrificing as little as possible and to do this with the least possible danger. A thorough knowledge and appreciation of the pathologic processes which occur in the pelvis, with the changes resulting when these processes have run their course, is essential in order to properly appreciate the condition with which we have to deal. The operation of vaginal hysterectomy and vaginal celiotomy for pelvic disease has come to stay. With many it is a fad. The indications however for the vaginal operation should be and are secondary to those for abdominal section. A complete operation by the vaginal route is difficult as adhesions are left behind, portions of tubes, etc. Sacs fill up if left after this operation. When quick convalescence is spoken of it is only of surgical convalescence, never allow them to get up before end of second week. Sequelae more frequent after vaginal operation. More cases of fecal fistula and of vesical fistula; complications often go unseen. Ureters are often ligated and clamped. Hernia should not occur in properly closed abdominal wound, hernia do occur after vaginal operation, and which is easiest to treat. This operation is to be preferred in some cases, chief of which is the septic condition following puerperal cases. Other cases are best treated by combined method.

DISCUSSION.

DR. L. S. McMURTRY of Louisville—The correct position is midway between extremes. The pelvic operation is not a new one; Battey practised it in his first operations, and pelvic surgeons have never discarded this route as a mode of attack. This is especially true of severe cases which will not permit thorough operation by abdominal route; drainage is obtained through the vagina. It is necessary in pelvic surgery to do the operation by the method which obtains the best result; where there is the greatest preservation of structures compatible with good surgery; and to do that operation which will result in a complete cure not making it necessary to do an additional operation. The field for the vaginal operation is in conditions of inflammation of pelvic organs, not for fibroids; also in post puerperal cases where the uterus is septic and the surrounding tissues also, which is quick in development. The vaginal operation has been introduced into this country as a fad, and has been carried to an extreme as was the operation for ovariectomy when first introduced. The great advantage in pelvic surgery is knowing what has been done and to treat the convalescence

intelligently. No abdominal surgeon can indicate with precision what is the condition. When any organ is taken out by the vagina it is taken for granted that it is all out, that all pools of pus so often walled in by intestinal adhesions, are evacuated. Asepsis is more difficult to maintain as the field is between two sewers of the body and the bladder and rectum are more frequently injured. The majority of operators say that the abdomen had to be opened before the operation was completed. There is a field for the vaginal operation, but it is a narrow field.

DR. W. C. DUGAN of Louisville—If much fixation is present the abdominal route should be selected. Cannot tell where the adhesions are located when operation is done from below, one is working in the dark. Often have to leave an ovary or portion of one and the operation is not complete. The patient must be left for a second operation or a combined one done. The pus in ordinary gonorrheal pus tubes in 90 per cent. of cases is innocuous. The patient after any operation, either abdominal or vaginal, should stay in bed two or three weeks, and if this was insisted upon there would be fewer cases with an infiltration in the broad ligament. Time is not a factor and this argument should not be used. With the clamp, accidents do occur; they slip if put on high up.

DR. W. H. WATHEN said that two years ago he was as much opposed to vaginal hysterectomy as they who had opposed it in discussion. The same objections would not be urged if these men would do the operation. He had wounded the intestine above but once.

DR. A. M. CARTLEDGE stated that he expected to see the men retreat and the pendulum swing in the other direction. It is almost suicidal to allow these patients to get up in ten days after the operation. Fecal and urinary fistulae is much more common in vaginal operation because one can not see work done, it is in the dark.

DR. LOUIS FRANK said that none opposed the operation of vaginal hysterectomy, but it was to the indiscriminate use of it. In sub-peritoneal fibroids there is no use of doing a hysterectomy as it can be removed by doing a myomectomy.

DR. M. F. COOMES of Louisville exhibited a case upon which an operation of gastrostomy had been done, the tube being still in situ. The child had swallowed lye, a stricture resulting, for six days it had not swallowed anything. It was fed by rectum for twenty-four hours preparatory to operating. The valve operation was done and there never was any leakage until two weeks ago, when after playing violently the tube had been misplaced. The child can swallow milk and water, a little at a time now. No dilating of the esophagus has been done.

Here followed a paper by Dr. R. B. Gilbert of Louisville, on

THE CARE OF PREMATURE INFANTS.

Statistics show 20 per cent. of infants born at sixth month have survived; 35 per cent. at seventh month and at eighth month 85 per cent. It is too often the custom to turn premature infants over to old women, without any attention. A physician is inexcusable if he allows a premature infant to die from sheer neglect. To preserve their life especial attention must be paid to the maintenance of bodily temperature, proper feeding, prevention of injury by handling. Maintain temperature at 100 degrees, evaporation of moisture goes on from body no matter how closely wrapped in cotton or clothing. Incubator is best method of maintaining bodily temperature. The one recommended consists of two tin boxes, with two inch space between for warm water. Water heated by coal oil lamp placed under small copper water box connecting with water chamber by small pipes. The top of the box is open to allow infant air and light. Any tight box may be improvised. Feeding is important, mother's milk best; gavage may be used. A mixture which has proved successful in author's hands is as follows:

Sweet milk, fresh	$\frac{3}{4}$ ij	60
Cream, fresh	$\frac{3}{4}$ ij	90
Warm water sterilized	$\frac{3}{4}$ x	300
Sugar of milk	$\frac{5}{8}$ j	4
Common salt	9 j	130

Above diluted for premature infant. Anoint infant after birth with warm lard, vernix to be wiped off; no water used at first cleansing. Premature infant not washed until three weeks of age.

DR. ARCH. DIXON, Henderson, reported

A CASE OF PLACENTA PREVIA.

The patient was six months pregnant, had a severe hemorrhage, a placenta previa was found, the membranes being intact. She had had two previous attacks of bleeding. Membranes were ruptured, feet brought down and after coming head delivered by short forceps. The mother rallied and made a

good recovery. The fetus was living though asphyxiated. It was eleven inches long and weighed a fraction over two pounds. It was swathed in cotton and surrounded by hot water bottles. In lieu of an incubator it was placed in a wool bag containing hot water bottles, it was fed by dropper on mother's milk. The child thrived and grew and to-day is one of the prettiest babies in the State, at four months weighing eight and one half pounds.

DR. T. B. GREENLY of Meadow Lawn, read a paper upon

RESUSCITATION OF STILLBORN INFANTS.

In the practice of fifty years only three or four cases of still birth could be recalled, save those which had to be eviscerated. Cold water thrown on face of asphyxiated infant, placing in water, temperature of 115 to 120 degrees, and artificial respiration. Considerable time may be spent in latter. Marshall Hall's and Sylvester's methods recommended, retraction of tongue, wiping out mucus in mouth. Schultz's swinging method frequently successful.

DR. J. A. LARRABEE, Louisville—The remarkable tenacity of infants to life must be noticed at a time when resuscitation must be done. The best method is that of Credé. Marshall Hall's method is rarely properly applied, the artificial respiration being too often made.

DR. J. G. CARPENTER, Stanford—A method used which is of service is to take hold of tongue with forceps. Invert patient on head and employ artificial respiration.

DR. JNO. G. CECIL of Louisville—The case presented by Dr. Dixon is one of extreme interest, it was surrounded with the gravest complications and it should go down on the annals of obstetrics as simply wonderful. The subject of incubators is certainly interesting and this treatment has been much neglected. There are several reasons why children do not breathe promptly, it is frequently because they strangle from mucus in the mouth. All artificial respiration may fail if this is not removed. It can be removed by a catheter introduced into naso-pharynx and larynx and drawn out by mouth. A child delivered by forceps after long labor suffers from a congestive asphyxia and if the cord is cut and allowed to bleed the blood pressure is relieved.

DR. R. B. GILBERT of Louisville, in closing the discussion said that a tobacco smoker or user may kill child by blowing nicotin in air passages of child when insufflation is practiced. Dr. Dixon's case is remarkable.

AFTERNOON SESSION.

The following papers were read by title: "Eye Strain," by Dr. P. Richard Taylor of Louisville, and "Punctured Wounds of the Eye," by Dr. A. G. Blincoe of Bardstown. Dr. J. G. Carpenter of Stanford, read a paper upon "Appendicitis with Purulent Peritonitis."

DR. R. D. PRATT of Shelbyville, read a paper entitled

A STUDY IN APPENDICITIS.

He reported fifteen cases, twelve of which recovered without operation, three died, one without operation, two after. Only four cases were in females, age from eleven to sixty years. Recurrence occurred in four cases. All cases are not believed to be surgical. They may be so considered in larger cities, but not so in small towns or country. No one should go into cavity without special training. Surgical cases represented as those in which, 1. There is rapid destruction of appendix and quickly developing septic or purulent peritonitis. 2. Moderately severe onset in which the symptoms do not yield in few hours to treatment or gradually getting worse indicating peritonitis or sepsis. 3. Cases with initial symptoms which rapidly disappear, there persists a condition simulating a pyemia or septicaemia. 4. In the recurrent cases where attacks are getting more and more frequent. Saline treatment should always be used, never opium. But abscess may be ruptured by increased peristalsis.

DR. F. N. BAUGHMAN of Flat Lick—Nearly all surgeons tell too much about how to do the operation and leave too much for granted as to the after-treatment. Aristol is an excellent remedy to use to prevent re-adhesions when put over inflammatory surfaces. As to drainage, aseptic gauze is the best we have. To prevent hernia the Halsted woven wire suture should be considered.

DR. A. M. CARTLEDGE of Louisville—Appendicitis is evolved by series of lesions. Is a case well when abscess ruptures in intestine? They subsequently have trouble due to the appendix abscess filling up, giving a train of symptoms generally thought to be recurrent appendicitis.

DR. H. H. GRANT of Louisville—Too little is thought of appendicitis; in all cases of this trouble it is a foreign body inflammatory, suppurative and gangrenous. It is removed safely and easily if under favorable conditions and if instituted

early little harm can come, but it is generally fatal if there is neglect to do so.

DR. ARCH. DIXON of Henderson believes that appendicitis is an acute septic, infectious disease from the start. It is the duty of the physician as soon as diagnosis is made to call surgeon and do the operation. It is a surprise to see Dr. Hunter McGuire say that it is best to wait and see what the patient will do. Operate as soon as the diagnosis is made.

DR. J. G. CARPENTER of Stanford—Pus in the abdomen demands prompt surgery. Patients however do recover without operation. Conservative surgery is what is needed, not meddlesome surgery. No reason why the general surgeon should not operate. The drainage tube and gauze are both good as drainage.

DR. R. D. PRATT of Shelbyville stated that few general practitioners are capable of doing an abdominal operation; these should be relegated to the specialist. All cases of appendicitis are not surgical; of the twelve cases, twelve recovered with medicinal treatment, one case following rupture of abscess in intestine, and in three years had no recurring attack. Opium should never be given unless absolutely necessary.

A paper was read by DR. AUGUST SCHACHNER of Louisville, on "Transfusion, Infusion and Autofusion."

DR. J. C. CARRICK of Lexington, contributed a paper upon

GONORRHEA IN THE FEMALE AND ITS TREATMENT.

The discovery of the gonococcus has been a great help in study of this disease. Gonorrhea in female has a tendency to pass through rapidly acute stage into the chronic. These patients are generally sterile, they have great discomfort and pain and health is impaired. There is an exudative inflammation of the submucous connective tissue; blood vessels undergo abnormal enlargement. In treatment disinfect urethra, peri-urethral glands, Bartholin glands, vagina and uterus, with rigid antisepsis.

DR. C. B. SCHOOLFIELD of Dayton read a paper on
CHOLELITHIASIS.

The predisposing causes are invalidism child-bearing and abdominal tumors. They are formed in gall bladder and hepatic duct, principal composition is cholesterol and epithelium from mucous membrane and occasionally bilirubin. They may number one or a thousand. First intimation of gallstones is usually biliary colic, lancinating tearing pain located over right hypochondriac and epigastric region. Gastric symptoms usually most prominent, pain greatest when food passing from stomach into duodenum. Jaundice occurs in only about 50 per cent. of cases. Movable kidney difficult to differentiate. Kidney movable, pain follows ureter. Medical treatment give remedies which increase rapidity or flow of bile; course of treatment at Mineral Springs recommended. Surgical treatment, when demonstrated beyond a doubt; the case is not medical but becomes surgical at once. Before obstruction of ducts cholecystotomy is one of the easiest operations, and one of the most successful. If obstruction occurs it is difficult and dangerous. Preparation of patient same as recommended in other abdominal operations.

DR. A. M. CARTLEDGE of Louisville—In fifteen cases operated upon, jaundice was a symptom in only two. One was pronounced, obstruction being in common duct, and was the only death in the series. It is a most common affection, and is confounded with dyspepsia. In operating a misplaced kidney may be gone down upon, and it has been found that the symptom usually described, of tumor moving with the diaphragm is not a good one, and not a diagnostic symptom. Exploratory operation is the step to take to clear up the diagnosis. The operation promises to be the most successful of all abdominal operations.

DR. W. C. DUGAN of Louisville Jaundice rarely found, and when found can invariably tell patient that it is not in the cystic duct but in the hepatic or common duct. Removal from the cystic duct is easy, from the common duct very difficult. Local tenderness and muscular rigidity are important symptoms. The incision when operating must be made through the median line or the muscle. The greatest danger lies in the irrigation, this being either done too soon or allowed to flow too fast as to tear the anchoring loose. The water should flow out as fast as it flows in.

DR. C. B. SCHOOLFIELD in closing stated that the dyspeptic symptoms are the most prominent ones; the pain comes on some time after the ingestion of the food when it is passing from the stomach into the duodenum. Jaundice is seen but in a few cases.

DR. L. S. MCMURTRY of Louisville presented a paper upon "Modern Gastrostomy for Stricture of the Esophagus, with Report of Case." This paper will appear in the JOURNAL.

DR. J. A. STUCK of Lexington, presented a paper on

DISEASE OF THE ACCESSORY NASAL CAVITIES.

Far more frequent than formerly thought, many old catarrhal patients continued to suffer long after removal of all visible obstructive and diseased tissue in nasal and pharyngeal-nasal cavities: 1. Acute suppurative sinusitis with complete occlusion of normal outlet. 2. Chronic suppurative sinusitis with moderately obstructive openings. 3. Myxomatous or polypoid degeneration.

Transillumination with electric light is aid to diagnosis; it is not certain but enough to justify exploratory incision, with small burr attached to dental engine, small sharp curette or cutting forceps. Lamp is six-candle power. Frontal sinuses illuminated by using small one candle power lamp, over which is drawn a piece of rubber tubing, allowed to project about one-third of an inch beyond lamp. This free end is placed under the orbital plate of frontal bone near the inner canthus, the eye being kept closed. Several interesting and illustrative cases were reported.

DR. DUDLEY S. REYNOLDS of Louisville long since abandoned opening the antrum through the canine fossa; the teeth press up, carry the bone with them and as far forward as the canine fossa; the antrum is narrow and the cavity sets down below the line of the insertion. Best to open below this line through the second molar, using incision through soft parts and the bone, drill the opening large enough to permit good drainage and injection of disinfection fluid, peroxid of hydrogen and bichlorid of mercury; the latter, 1 grain to 1 ounce of water.

DR. T. C. EVANS of Louisville—Little was said about the fact that the greatest number of acute cases get well, if uncomplicated with polyps in nose or carious teeth, without operation or washing out through the maxillary sinus. The second molar tooth is best place for drainage, turning over to dentist to do operation and inserting gold tube.

TREATMENT OF TRACHOMA AND ITS COMPLICATIONS.

Subject of a paper by DR. T. C. EVANS of Louisville—Consideration limited to treatment of trachoma proper, embracing the medical and surgical treatment of essential lesion of disease, the true granulation or "sago," of complications embracing various forms of ulcerative keratitis, photophobia, pannus and eczema of lids; those sequelae embracing opacities, staphyloma of cornea, xerosis and cicatrices of conjunctiva, deformities of tarsus, ptosis, trichiasis and distichiasis of lids. Medical treatment consists in local application of escharotics, stimulants, astringents and antiseptics. Most common are sulphate of copper, bichlorid of mercury, ammonia, muriate, yellow oxid of mercury, tannin and boric acid. Bluestone oldest remedy. Thoroughness and duration of application important. Wash of boric acid in addition to copper. Time necessary to obtain cure is longer than usually supposed. Of surgical methods in use two may be mentioned: Excision of cul-de-sac and operation by expression or squeezing. In the latter operation the doctor should wear eye-glasses to protect his own eyes. The after-treatment should consist of ice cloths and proper antiseptic precautions for forty-eight hours; routine escharotic being resumed later. The ideal treatment is the combination of the medicinal and surgical, and the patient should be impressed with the fact that the operation will not be the end of his trouble. At best it is a dangerous disease and the treatment will be tedious.

DR. G. G. THORNTON of Gravel Switch followed with a paper on

THE SCIENTIFIC AND COMMON-SENSE TREATMENT OF TYPHOID FEVER FROM AN ETIOLOGIC AND PATHOLOGIC STANDPOINT.

If seen early the prognosis in cases that are not complicated from the beginning should be favorable and the mortality should be nil if given the proper treatment, medicinal and hygienic. There is not any doubt in anyone's mind as to the germ origin of the disease. The germ may pass in the dry state by inhalation into the fauces, by means of water and milk. The disease is primarily local, and is systemic only after the absorption of the typho-toxin. Its insidiousness is explained by the origin of the toxins. Typho-malarial fever is a misnomer in this section. An early diagnosis is of importance. The first thing after a diagnosis is made or a suspicion of one, we must insist on patient going to bed. Put system in the best possible condition for the battle with disease on one hand, and his powers of resistance on the other; $\frac{1}{2}$ grain of calomel every hour for three doses, then every two hours till good, free evacuation is produced; the diarrhea, if continued, control by opium and bismuth; to relieve the headache and backache, etc., acetanilid and salol. See that patient is kept quiet and free from annoyance by over-anxious friends. If sleep does not come naturally give chloral hydrate or tr. opii deod. By rendering the contents of the bowel aseptic by the use of anti-

septics, we make it unhealthy for any wandering germ to live. Salol, sulpho-carbolate of zinc and acetanilid are the best under the class of antiseptics.

Dr. JOHN G. CECIL of Louisville—It is not necessary to enter fully into the discussion of a subject on which we so entirely agree. However, acetanilid for the fever and headaches is not so good as other remedies. The same results can be accomplished without the depressing effect on the heart by the use of water. Brand's method is one of the most effectual methods of treatment and we can control the fever absolutely, or at least as much as we desire. No one claims that water depresses the heart, but this can not be claimed of acetanilid.

Dr. J. M. RAY of Louisville presented a paper on

OBSERVATIONS UPON EYE DISEASES AND BLINDNESS IN THE COLORED RACE.

The proneness of the negro race to develop thoracic diseases, tubercular manifestations, the acquired and inherited results of syphilis and their lessened powers of resistance to diseases of colder latitudes is familiar to every physician. The negro of this locality is not the negro of the cotton fields and sugar plantation of the extreme South. A tabulated report of 1,000 cases of eye diseases, exclusive of defects of refraction was presented. There is a great frequency of difference in eye diseases of two races. Of the series 140 cases of lid troubles were found; not a single case of trichiasis or entropion was found. Of phlyctenular variety of conjunctivitis a large percentage occurred in the negro race. One hundred and seven cases of corneal diseases were found. The form most rife is relapsing destructive ulceration characterized by phlyctenular strumosis. In iris diseases there is proneness to gummatous infiltration to accompany the inflammation. Fifty-three cases of crystallin lens disease occurred, twenty-two in negroes. Negro practically exempt from uncomplicated squint, and when present it was secondary.

Dr. DUDLEY S. REYNOLDS of Louisville—"Negro" is a very indefinite term; it is not the pure-blooded African who has these diseases, but the mulatto. Trachoma is not a local disease, is not contagious, but the manifestation of miasmatic infection. The mixed-blooded negro furnishes the large proportion of clinical material in our section.

Dr. J. N. BAUGHMAN of Flat Lick—The mulatto race in medicine as in surgery has very little resistance. This is a fact demonstrated long ago.

Here followed a memoir prepared by Dr. Lyman Beecher Todd of Lexington on Dr. Orin D. Todd of Eminence, deceased.

EVENING SESSION.

The following popular addresses were made: "Vigorous Childhood Essential to Green Old Age," by Dr. J. A. Larrabee of Louisville. "The X Rays, illustrated by Experiments and Stereopticon Views," by Dr. Samuel E. Woody of Louisville.

THIRD DAY—MORNING SESSION.

Dr. C. C. LEWIS of Stamping Ground read a paper on

COMPOUND FRACTURES.

Regardless of inconvenience an anesthetic should be administered. The important question of amputation can not be decided without an anesthetic, except were there is complete destruction. Before days of aseptic surgery efforts at saving limb proved disastrous, but this element is not considered now. The rules of cleanliness should be applied with all possible emergency and there are no other grounds of safety. The plaster dressing offers fewer objections than any other mode of dressing, and is ideal when it can be aseptically treated and hermetically sealed. If of large size the wound is properly prepared by trimming edges, cleansing, etc., and the Bavarian splint presents many advantages. Hemorrhage must first be stopped, bichlorid, soap, water and brush being used unsparringly, preparing the limb as for amputation. Remove dressing in seven or eight days and if drainage tube is used it can be replaced by absorbable bone drain. The elbow joint and maxillary bone, when subject to violence as to cause compound fracture, require the closest attention. In maxillary fractures interdental splints are necessary. Do not investigate without an anesthetic. Give patient every possible benefit of a doubt in the question of amputation. Select aseptic methods of treating the wound; use a dressing which will give the patient the greatest comfort, the plaster dressing.

The Nominating Committee submitted the following report, which was unanimously adopted: President, Dr. R. C. McChord, Lebanon; First Vice-President, Dr. H. C. Lassing, Union; Second Vice-President, Dr. Arch. Dixon, Jr., Henderson; Secretary, Dr. Steele Bailey, Stanford; Treasurer, Dr. J. B. Kinnard, Lancaster; Librarian, Dr. Frank Boyd, Paducah. Owensboro was selected as the next place of meeting.

A resolution of thanks was extended the railroads, the hotel, the ladies, and Mr. R. W. McElroy for the admirable entertainment and to Dr. J. A. Lewis, the President, and Dr. R. C. McChord, Chairman of the Committee on Arrangements, for their able administrative efforts.

On motion, the vote making disposition of the report of Committee on Codifying the Constitution was reconsidered and all save that part relating to the election of officers was adopted. The latter was made to lie over until the next meeting.

The Nominating Committee submitted a subsequent report nominating the following as a Board of Censors: Drs. B. L. Coleman, Lexington; John G. Cecil, Louisville; T. B. Greenly, Meadow Lawn.

Dr. JOHN MASON WILLIAMS of Louisville read a paper on

THE SCOPE OF COLOSTOMY IN CANCER OF THE RECTUM.

The operation should be considered only as an advanced palliative treatment. If seen early cancer of the rectum is subject to removal. The rational treatment of the train of symptoms which follow cancer of the rectum is colostomy. These symptoms which demand relief are hemorrhage and pain. Left inguinal and lumbar methods are the operations done; the former the best, the chief, because it is an easy matter to see every step of the operation and inspect the bowel before incising. The anus is in front and can be attended to easily.

The President appointed the following committees: On Publication, Drs. H. A. Cottell, Louisville; M. F. Coomes, Louisville; Henry E. Tuley, Louisville. On Public Policy, Drs. J. B. Marvin, Louisville; David Barrows, Lexington. J. N. Baughman, Flat Lick.

The following resolution was introduced by Dr. John G. Cecil and unanimously adopted:

WHEREAS, Many of the important life insurance companies have reduced the medical examination, and

WHEREAS, Doctors have very generally received scant remuneration for this responsible work, which taxes their skill and time, be it

Resolved, By this Society that on behalf of the members of the Kentucky State Medical Society and of the physicians of Kentucky, we protest against this reduction of the ordinary fee for examination of \$5 on the part of the insurance companies, and that we request all doctors of this Society engaged in making life insurance examinations to exact a fee of \$5 for each examination.

Upon motion and discussion this was finally adopted.

SOCIETY NEWS.

The Central Iowa Medical Association held its twenty-second annual meeting in Boone, June 19. Papers were presented by Drs. Wright, Nostrom, Allen, Ensign and others. The officers elected for the ensuing year are: A. A. Deering, Boone, president; F. E. Whitley, Webster City, vice-president; G. H. Stanges, Boone, secretary and treasurer. Ames was selected as the place for holding the next meeting.

The Delaware District Medical Society, Indiana, which was in session at Dunkirk, June 15, adjourned to meet next year at Anderson. The officers elected were: President, J. B. Garner of Dunkirk; vice-president, B. S. Hunt of Winchester; secretary and treasurer, Fred J. Hodges of Anderson. Professors Senn of Chicago, Parvin of Philadelphia and Klebs of Berlin, delivered addresses.

The Third District Branch of the New York State Medical Association held their twelfth annual meeting in Auburn, June 11. There were about forty in attendance, representing the counties of Broome, Cayuga, Chemung, Chenango, Cortland, Delaware, Madison, Onondaga, Otsego, Schuyler, Seneca, Tompkins and Tioga. The next meeting of the association will be held at Norwich.

West Virginia State Medical Society.—At the annual meeting of this society held at Wheeling, June 10-12, N. D. Baker, M.D., of Martinsburg, Secretary of the State Board of Health, was elected president for the ensuing year. The next annual meeting will be held in Charleston. The next regular meeting of the State Board of Health will be held in Charleston, about

the middle of July, for the examination of candidates for practice of medicine and other business.

The Medical Society of the County of Erie, N. Y., held its semi-annual meeting in Buffalo, June 9. The following papers were presented: "Acute Epiphysitis," Nelson G. Richmond of Fredonia, N. Y.; "Refraction without Mydriatics," R. H. Saterlee; "Early Treatment of Mental Disease," A. W. Hurd. Superintendent Buffalo State Hospital; "Forced Breathing and the Pneumatic Cabinet," J. H. Pryor.

The American Microscopical Society will hold its nineteenth annual meeting in the new Carnegie Library Building, Pittsburgh, Pa., Aug. 18, 19, 20 and 21, 1896. A hearty welcome will be extended to all interested in the microscopic sciences. Applications for membership and titles of papers to be read at the meeting should be addressed to A. Clifford Mercer, M.D., president, Syracuse, N. Y., or to Wm. C. Krauss, M.D., secretary, Buffalo, N. Y.

The British Medical Association Congress at Carlisle.—Dr. Henry Barnes of Carlisle has been appointed as acting president on account of the death of the president, the late Sir Russell Reynolds. The arrangements for the Carlisle meeting of the British Medical Association at the end of July are in a forward state and there is every reason to anticipate a successful session. Dr. Barnes is the physician to Cumberland Infirmary, and he has chosen one of his colleagues, Dr. Roderick Maclaren, to deliver the address in surgery. It is understood that Dr. Maclaren will devote one section of his address to some comments upon the new aid to surgery presented in the discovery of the X photographic rays. Of the nine sectional presidencies, four will be filled by local practitioners.

Pacific Coast Association of Insurance Examiners.—The second annual meeting of this association was held in Portland June 9. The president's address was delivered by J. B. Eagleson, M.D., of Seattle, Wash. The following officers were elected for the year, viz.: K. A. J. Mackenzie, M.D., Portland, Ore., president; Drs. W. J. McGuigan, Vancouver, B. C.; Benj. R. Swan, San Francisco, Cal.; C. L. Sweet, Boise, Idaho; J. M. Sligh, Granite, Mont.; W. F. Amos, Portland, Ore.; Samuel C. Baldwin, Salt Lake City; G. S. Armstrong, Olympia, Wash., vice-presidents for their respective States; Henry W. Coe, M.D., Portland, Ore., secretary. The next annual meeting will be held at Spokane in conjunction with the Washington State Medical Society, in May, 1897.

Massachusetts State Medical Society.—The one hundred and fifteenth annual meeting of the Society was held in Boston, June 9 et seq. There was a large attendance of members. The Shattuck lecture was delivered by Dr. W. W. Keen of Philadelphia, on "The Surgery of Typhoid Fever." He gave especial attention to the subject of gangrene. That typhoid fever had important surgical relations was now recognized by the profession. English and American authors had not in the past given the necessary attention to the appearance of gangrene after typhoid. The chief knowledge of it came from French authors and from a few English and American publications. Gangrene was possible in both mild and severe cases, yet it was happily of rare occurrence—at the rate of four cases annually for the past fifty years. Officers were elected for the ensuing year: President, H. P. Walcott of Cambridge; vice-president, A. Wood of Worcester; treasurer, C. M. Buckingham of Boston; secretary, F. W. Goss of Roxbury; recording secretary, C. W. Swan; librarian, Edward H. Brigham; orator, Z. B. Adams of South Framingham.

Oregon State Medical Society. The 23d annual meeting of this Society was held at Portland, June 9 and 10. The following papers were read and ably discussed, viz.: Address of Welcome, by A. C. Smith, Portland; "The Family Sponge and How to Clean It," by O. H. Beckman; "Some of the Phases of Criminal Abortion," by Richmond Kelly; "Varicocele," by M. Fried; "Slight Ailments," by J. A. Geisendorfer;

"Cases of Appendicitis," by A. C. Panton; "The Roentgen Rays and their Application in Medicine and Surgery, with a Demonstration," by J. C. Perry, U. S. M.-H. S.; "Mechanism of the Knee Joint," by R. Nunn; "Surgery of the Gall Bladder," by K. A. J. Mackenzie; "Double Castration for Hypertrophy of the Prostate," by David H. Rand; "Inflammation of the Iris and the Ciliary Body," by W. L. Wood; "Treatment of Septicemia, with Report of Cases," by C. J. Smith; "Infantile Mortality due to Impure Milk," by Otto S. Bismwanger; "Suppurative Osteo-myelitis," by F. Cauthorn. The president's annual address was delivered by O. D. Doane.

BOOK NOTICES.

A Manual of Physiology with Exercises. By G. N. STEWART, M.A., D. Sc., M.D., Edin., D. P.H. Camb., of Downing College, Cambridge; Professor of Physiology in the Western Reserve University, Cleveland, etc., etc., with numerous illustrations including five colored plates. London: Bailliere, Tindall and Cox, 1895. 8vo, pp. 796.

In the gradual change now going on in medical education in this country, this physiology is especially welcome. It is a carefully prepared series of exercises illustrating the more important problems of physiology with special reference to their bearings upon the future study of clinical medicine and diagnosis. The book shows how it was prepared and gives one to understand at once that no great effort has been made to follow the customs or prejudices of American medical teaching. Its only concession in this direction seems to be the order of the material of each chapter. The descriptive portion comes first and somewhat resembles an old text book, then follow directions for laboratory exercises. The true pedagogic order would seem to be the laboratory exercises then the descriptive portion. These exercises are practical and every one significant. They have evidently been chosen after experiment with a class of students, in an American medical college. A few of these exercises require apparatus which some colleges could not easily obtain. For the most part the apparatus is simple and could be constructed by the students themselves in an ordinary laboratory workshop. Indeed this preparation of apparatus is very desirable. This book can be recommended to any teacher of physiology as a work likely to give him that necessary guide which will permit a change from the old lecture system to the laboratory method of teaching physiology. The smaller medical schools have a decided ally in this book in their effort to rival the larger metropolitan schools in instituting better and more effective methods of teaching.

Transactions of the Royal Academy of Medicine in Ireland, Vol. XIII, 1894 and 1895, 464 pages. Edited by WILLIAM THOMSON, M.A., F.R.C.S., General Secretary, Surgeon to the General Hospital, Dublin, Ireland. Printed by Fannin & Co., Limited, Grafton Street, Dublin. The contents includes lists of officers and members, etc.

The sections of medicine, surgery, etc., contains forty-nine papers. H. C. Tweedy, M.D., F.R.C.P., reported a case of argyria on account of its comparative rarity, the prolonged use of nitrate of silver in locomotor ataxy having declined. The patient first came under his observation in 1871, suffering with well marked ataxic symptoms. He was ordered $\frac{1}{8}$ grain nitrate of silver three times daily. This treatment was continued at intervals till 1876. In 1882 he again appeared at Steevens Hospital, when the change in his complexion to a dull slaty blue was noticed for the first time. The ataxic symptoms had, however, disappeared.

Injuries of the Thumb, by Edward H. Bennett, M.D., F.R.C.S. He described the various dislocations of metacarpophalangeal joint and submitted an example of complete dislocation inward of the phalanx which he believed to be the only case yet observed.

Arthur Benson, M. A. University Dublin, F.R.C.S., submitted report of cases of acromegaly with ocular complications. The papers are carefully prepared and, of general interest.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 61 Market Street (Occidental Buildings), Chicago, Illinois.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

INFORMATION WANTED.

It would greatly facilitate the prompt delivery of the JOURNAL to those members of the Association living in large cities, if they would kindly furnish this office with their street address in those cases where it is omitted from the wrapper of their JOURNAL, as we have been notified by the postmasters of the larger cities that second-class mail matter not having street address, would be placed in the general delivery to await call.

SATURDAY, JUNE 27, 1896.

CLOSE OF VOLUME TWENTY-SIX.

With this issue we close twenty-six volumes of the JOURNAL OF THE ASSOCIATION—covering a period of twelve years of American medical literature—and comparing the volume just closed with its predecessors, we can freely say that the improvement has been steady from its commencement. Indeed, the growth of the JOURNAL in the last year has been phenomenal; the current volume contains about three hundred pages of reading matter more than any of its contemporaries, and double the number of pages of reading matter found in some of the weekly journals. That the ASSOCIATION can maintain a first-class medical weekly is therefore self-evident, and its wonderful growth in the last year must be taken as simply a prelude to the development that is to come in the near future. Its broad pages teem with brilliant suggestions not only from the members of the ASSOCIATION, but from the keenest observers throughout the medical world.

The next volume will begin with an enlarged JOURNAL—eight pages of reading matter each week will be added—and without boasting of future performances, we can only promise that the material in the enlarged issue will be equal, if not superior, to that published during the last three years.

We have one satisfaction in this work, and that is the sincere sympathy, kindly forbearance and the hearty encouragement the present editorial management has received from the ASSOCIATION itself, and it is cer-

tainly true to-day, as never before in the history of the ASSOCIATION, that the ASSOCIATION is alive to the necessity for enlarging and extending the power and usefulness of the organization, and the considerable increase in members that has taken place in the last year should serve as an incentive to renewed exertions and harder work on the part of each and every member of the ASSOCIATION. There is no reason why the AMERICAN MEDICAL ASSOCIATION should not have fifty thousand members. There is no reason why the power and influence of the ASSOCIATION should not be felt in all matters of National legislation, even more in the future than in the past, and we should strive by all legitimate means to enroll every worthy member of the profession under the banner of the great National organization. Let us all work to that end.

Let us have a Department of Public Health.

AN EXPLANATION IS IN ORDER.

At the recent sparsely attended National Conference of State Boards of Health, held in Chicago June 10-12 inst., one of the topics for discussion was the necessity for a "National Department of Public Health," the topic being proposed by the State Board of Health of Alabama and the discussion, according to the program, was to have been opened by Dr. J. N. McCORMACK of the Kentucky State Board of Health. In Dr. McCORMACK's absence the discussion was opened by Dr. JEROME COCHRAN of Alabama, who spoke at considerable length in advocacy, not of a National Department, nor even of an independent Bureau of Public Health, but of a sub-bureau of the Marine-Hospital Bureau, with its chief officer to be appointed by the Supervising Surgeon General of the Marine-Hospital Service.

Naturally there was considerable surprise among such of the delegates as had given the subject thoughtful consideration and Dr. HENRY B. BAKER of Michigan rose to reply with the intent to bring the discussion back to the topic proposed, to-wit, the desirability of a National Department of Public Health. So much time, however, had already been consumed in setting forth the claims of the proposed sub-bureau that Dr. BAKER was requested to be very brief and, as a matter of fact, no discussion in opposition was permitted. Dr. COCHRAN, being again awarded the floor, asked that each State Board of Health appoint a committee to act with himself as Chairman of the whole, to labor for the creation of this sub-bureau. On a motion to adopt the recommendation of Dr. COCHRAN, Dr. BAKER moved as a substitute that the Conference appoint a special committee to co-operate with the committee of the AMERICAN MEDICAL ASSOCIATION and with the similar committee of the American Public Health Association. This substitute was rejected by a vote of 8 to 5 and Dr. COCHRAN's plan was then adopted—presumably by the same vote,

that is, eight delegates out of a total of some forty-odd who should have been present.

DR. BAKER and the other four delegates who voted with him were careful to state that they had no desire to oppose any movement that promised advancement in public health administration by the National Government and that there was no objection, *per se*, to the elevation of the Marine-Hospital Bureau to the dignity of a Department of Public Health; but they condemned the proposition to place the public health affairs of a continent in charge of a *sub-bureau* or division as belittling the whole movement.

The JOURNAL trusts that it has been misinformed as to the facts and that a mere majority of this baker's dozen of delegates has not assumed to commit the health boards of forty-five States and the Canadian provinces to this retrograde action. A telegram to the Secretary of the Conference requesting a copy of the proceedings elicits the fact that he is on a vacation. We forbear further comment until after a perusal of DR. COCHRAN'S argument.

Let us have a Department of Public Health.

THE BACTERIOLOGIC AND CHEMIC TESTS OF DRINKING WATER.

It is probably correct to assume that at the present time there is a strong tendency amongst physicians to overestimate the importance of bacteriologic diagnosis as compared with that by other long-used methods, and this tendency finds expression not only in common practice, but is encouraged to some extent by the writings of high authorities. The term "overestimate" is here used advisedly because, with all its value, the discovery of actual germs is not everything in itself and is, moreover, often difficult or impracticable while other methods are available.

Within the past few months or a year, there have been several papers and memoirs published that have a bearing on this question. An English authority, PROFESSOR HANKIN, sent out a pamphlet the object of which was largely to magnify the importance of the bacteriologic over the chemic tests in the examination of drinking water, and on the other hand, DR. DUPRE in England and MR. W. P. MASON in this country, have in their publications upheld the importance of the chemic analysis. FLUGGE in Germany, and THRESH in England, rightly insist that neither the microbic nor the chemic examination of samples is sufficient without attention to the sources of the supply and all its surroundings. This, however, does not do away with the use of either of the two methods, and in case of suspected sources of drinking water, such as wells or springs, the question still remains: On which shall dependence be placed? Some time since, the London Board of Public Works sent out to several chemists samples of water purposely infected with typhoid germs for analysis, and as in each case

the water was reported as pure, this has been used as an argument against the value of chemic examinations. It is possible that a still later examination microscopically might have also failed to detect the introduced germs, for chemically pure water is a poor culture medium, and according to good authorities, bacterial life will not thrive in it. At any rate, the experiment proves nothing without this test and, with it, would still be inconclusive.

The chemic examination of drinking water demonstrates the possibilities of its infection by morbid germs, and therefore, as DR. DUPRE and MR. MASON have shown, enables us to anticipate danger even if it may not be actually present. It is moreover, in its simpler forms, generally practicable and available and, so far as it goes, covers the whole ground, while it is not certain that we have yet discovered all the germs and the methods of their detection in water-borne disease.

Notwithstanding the great advances that have been and are constantly being made in the bacteriologic examination of water, we are not yet prepared to do without the careful chemic analysis in estimating the dangers of its pollution. And, inasmuch as prevention is better than cure, the discovery of the conditions that favor bacterial growth in water is of more importance than waiting till the actual appearance of the germs of disease, in forming a judgment as to its safety.

It must not be understood that the use of bacteriologic tests is here decried. Their value is beyond question, but with our present knowledge and methods they can not entirely supplant, and can indeed often only supplement, the well tried methods of chemic analysis. Each method has its special value, but the chemic test has still in some respects the widest utility. Let us have a Department of Public Health.

ANTITOXIN.

We will next week publish in full the report on antitoxin of the American Pediatric Society, as prepared by a committee and adopted by that body. The subject is full of interest, whether one agrees with the report or not.

Let us have a Department of Public Health.

CORRESPONDENCE.

Did He Sham On The Gallows? A Review of the Windrath Case.

CHICAGO, June 22, 1896.

To the Editor:—Joseph Windrath, a German 29 years of age, married, three children, an expert machinist, was hanged in Chicago June 5th last for the murder of a very popular man, the cashier of the West Chicago Street Ry. Co., when committing a robbery with an accomplice. The sentence set the execution for May 15th, but a reasonable doubt of his sanity being established since the date of sentence a respite was granted for a trial on that score, as the law of Illinois does not

permit the execution of a lunatic. The State charged that he was shamming insanity and presented six medical witnesses, viz: Drs. N. S. Davis, Sanger Brown, Archibald Church, Walter Kempster, James Lydston and Dr. Fortner who is the jail physician, all of whom testified that he was both sane and shamming. On the other side Drs. Florence Hunt, O. S. Waters and myself testified that he was insane.

I first examined Windrath at the instigation of his attorney on April 30 in a private room in the jail in the presence of a keeper and was introduced to him as Dr. C— sent by his attorney. The examination lasted an hour. He was prompt, pertinent, coherent, distinct, fluent and comparatively composed throughout the interview. He had frequent slight twitchings of the face at different points and a very peculiar facial expression at moments, varying somewhat with the subject of conversation, and evidently an involuntary product, for although inexpressive of any normal emotion it was too spontaneous to be deliberate. In my questioning I drove him "hard and gentle," and attempted to mislead him by suggestions, but all to no purpose. I discovered no delusion excepting the perpetual motion idea, which he had entertained ever since a school boy and was still working upon. When I asked him why he killed his victim he instantly denied the charge and his eyes flashed a most peculiar and strong glare, by which more than any other one thing I recognized latent insanity—a centric instability—a deep seated neurotic state. His pulse was not normal in tone nor febrile nor inflammatory, and therefore was neurotic. I may state here that I have been fifteen years in general practice and ought to know the pulse. Such a thing as a neurotic pulse was denied by some of the experts for the State. Otherwise, as regards his physical condition and moral disposition, there was nothing worth mentioning. He was freely communicative. A few minutes after this general examination I made a visit to the prisoner's cell, unexpected by him, and asked to see his drawings of his perpetual motion machine. He promptly handed them to me and I found them very artistic drawings of a rather complicated and ingenious mechanism. His entire manner had changed and he took a very lively interest, speaking much more rapidly than before, explaining the modus operandi, minus, of course, initial motion and compensation.

As a result of this first examination I did not make a positive report of insanity, but as having the insane diathesis and being so unstable as to be liable to break down into unquestionable insanity at any time. In reality I believed him insane then.

At my second examination some ten days later I stepped to the side of the door of his cell, unknown to him, and watched him a few moments. He was pacing too and fro, but not noisy, though talking to himself or calling to imaginary objects. When I stepped in front of the cell door and called him by name he seemed for a moment to hesitate about coming to the door, but did so and obeyed my request to extend a hand through the bars that I might feel his pulse. His whole body was in a tremor and clammy. His pulse was 120 and neurotic. His face had a wild, confused stare, and he was partially irrelevant to questions, rambling and incoherent in speech, at times talking to voices or imaginary objects. He was stupid to some questions, but to others pertinent.

My third and last examination was ten days later, lasting only a few moments, the morning before I testified in court. He was in bed, but sat up and replied to questions, in a half stupor but more or less pertinent. On being questioned he said his wife and children had disturbed his sleep and he spoke of one or two other vagaries. His breath was distinctly neurotic, smelling somewhat like urine slightly tinged with feculent matter, and which I have never observed except in intensely neurotic cases. Even in such cases it is not always noticeable. It is most noticeable in cases of acute insanity, especially mania and melancholia. I probably would not have noticed it

this time had he not forcibly breathed into my face at my request. At my previous examination I had neglected this observation.

From his wife I learned that dating from about two years after marriage he began to act strangely at times, coming home somewhat intoxicated, she thought, when he would sit moodily for a considerable period and talk to himself and laugh and "work his face." In some of these spells he would be silent, only "working his face" as she called it. I examined Mrs. Windrath very carefully, as I was aware she had strong motive to falsifying. For instance I suggested that "he would sometimes come home insanely quarrelsome" but she promptly denied this, and many other suggestions I made to trap her. He also had hallucinations of hearing, at times, dating back several years, when he would charge his wife with calling to him on the street and other places while she was remote from him. I do not doubt these being facts.

Windrath's rather queer look at best would readily suggest to the ever suspecting police that he was a crook, especially if known to be idle or loafing, and it may be that he has been charged with more than is just. From my inquiries of the police authorities in regard to stories of other crimes I find them without any substantial foundation. Up to the close of the World's Fair, at which he was employed, he had been pretty regularly engaged at his business, but at the close of the Fair he fell into enforced idleness and bad company, soon got into the hands of the police on a charge of robbery, which was not fully sustained; and a month or so later was sent to the County Insane Asylum with acute melancholia. He remained at the Asylum about four and one-half months, where he has a clear record of mania and melancholia with delusions of sin, etc. He was discharged *improved*.

I witnessed his execution, but I can hardly do better than give the description of it by the *Daily News*: "The murderer made no struggle, as had been anticipated. He was led out a few minutes before noon, his arms tightly pinioned to his sides. With rolling eyes and blanched face the man presented a terrible sight, his closely cropped hair adding to his strange appearance. He shouted incessantly as the short preparations were being made, his cries being unintelligible. It sounded like 'han up! bishua.' Then his voice would deepen and he would mumble on: another change and he would seem to be trying to sing. Even after the white cap had been drawn over his head the cries continued and sounded muffled. Jailer Whitman tightened the noose about the man's neck, and his cries were slightly checked. A second later and he shot to his doom. The general opinion was that the man was hopelessly insane."

The experts for the State substantially said he was shamming because, 1, he presented symptoms of two forms of insanity, viz: melancholia and dementia, which they alleged never coexist; and 2, because his condition and conduct were perfectly natural under the circumstances, which, they said, he fully realized.

As regards the first reason, I will say that it is quite in conflict with my own asylum and private practice observations. Let us hear the recent words of one or two first-class authorities on this point. In the *British Medical Journal* of Sept. 28, 1895, page 760, Dr. Henry Rayner, editor of the *Journal of Mental Science* and lecturer on mental diseases, St. Thomas' Hospital College, London, England, says: "Clinically the pathologic unity of insanity is demonstrated by transitions from mania to melancholia or stupor (dementia), by sudden alternation of these states, by their occasional and *partial coexistence in the same case*, and in many other ways. Pathologically, owing to the recent advances in the histology of the cerebral cortex due to Golgi, Raymon y Cajal, Bevan Lewis, Hodge, Batty, Tuke, Andriezan and others, the close relationship of these conditions has become still more obvious."

In the *Lancet* (Lond.) of Jan. 4, 1896, Sir William Broadbent, Bart., President of the London Neurological Society and physician for the Queen, gives a case of "inability to recall the name of the most familiar objects presented to his sight, while he conversed intelligently, employing a varied and extensive vocabulary, making few mistakes, but occasionally forgetting names of streets, persons and objects." Along the same line Maudsley says: "Persons may be very defective (aberrant) intellectually, but very proper in conduct."

The experts for the State alleged that Windrath pretended to forget some of the most familiar things, but answered promptly about others.

As to the realization of acts and circumstances by the insane, if it is simply a question of knowing one thing from another, it must be admitted that they commonly realize about as much as most people. But if the question is as to the proper relationship of things the answer has to be in relative terms, according to the delusional state.

The experts for the State made their examinations of Windrath when his condition of greatest perturbation had subsided, and thus probably found him in a comparatively rational state. Dr. Florence Hunt, examining him about the same time, found his pulse 60 and so testified. Dr. Fortner, a witness for the State, found his pulse 120 a week or so before, when he was most disturbed. The other witnesses for the State said they found his pulse about normal when they examined him. He had no inflammatory or febrile condition whatever at any time, unless during his spell of greatest cerebral disturbance.

Among the peculiar features of the trial was the testimony of an expert ophthalmologist, which in substance was that blindness would affect the brain so as to stunt the development of the mind and preclude intellectual distinction. Had he never heard of John Metcalf, the distinguished mechanic, blind at 6 years of age; John Stanley, the eminent musician, blind at 2 years of age; the noted Helen Kellar, blind at 18 months; the famous Laura Bridgeman, blind at 2 years of age, and our own Dr. Babcock, blind at 9 years of age? This expert testified that Windrath's eyes were healthy and that the eyes of the insane rarely were so. This is something new, and I was not aware that the health of Windrath's eyes had been in question.

Another expert for the State defined insanity quite briefly but rather comprehensively as "a disease of the brain affecting the mind." Thus a headache is insanity. The same expert stated that Windrath spoke of imagining he heard certain voices, and said that a person with a real hallucination would not say he imagined he heard it, but that he *did* hear it. How is it when the hallucinations are gone and the subject realizes they were only imaginings? Will he still say that he hears them? Windrath did not have hallucinations when this expert examined him.

When Windrath was arrested a police inspector asked him if he was going to play his insanity game this time and told him if he was, to hurry up with it. This inspector informs me that he made him confess that he (Windrath), was no more insane than he (the inspector) was. A very natural, or at least usual, confession for a lunatic.

The State had able counsel, but the counsel on the other side was inexperienced in such cases and did not use any medical adviser. However, the jury held out for eight hours and at one time five favored a verdict of insanity.

It must be quite evident that a pure shammer would go to the gallows evincing either cowardice, bravado or repentance. Windrath, as the *Evening Post* stated, went "raving to the very last."

J. SANDERSON CHRISTISON, M.D.

Origin of Our Code of Medical Ethics.

NEW YORK CITY, June 17, 1896.

To the Editor:—Dr. Robert T. Morris of New York City, a member of the AMERICAN MEDICAL ASSOCIATION tells me that I can get a copy of the ethical code by preferring the request to

you. If the JOURNAL can do me this favor I should esteem it a great kindness.

And may I ask the further favor of a reference to some history of origins of the ethical code? The high standard of honor, and disinterested spirit, and devotion to mankind that animates physicians has always excited not only my admiration, but my curiosity as to where it came from. A profession is a means of livelihood, but their principles of honor are constantly in the way of doctors making money. It is as if the profession in early days had been a religious order. Knowing this now to have been the case my wonder was excited as to the history of the ethical code.

Begging pardon for thus trespassing on your time, I beg you to believe me.

Respectfully yours,

A. D. SAVAGE, M.D.

ANSWER:

The National Medical Convention, which assembled in New York in May, 1846,

Resolved, That it is expedient that the medical profession in the United States should be governed by the same code of medical ethics, and that a committee of seven be appointed to report a code for that purpose, at a meeting to be held at Philadelphia, on the first Wednesday of May, 1847.

At that meeting (Philadelphia, June, 1847); the committee, appointed under the sixth resolution adopted by the convention which assembled in New York in May last to prepare a code of medical ethics for the government of the medical profession of the United States, respectfully submit the following code:

JOHN BELL,	} Philadelphia.
ISAAC HAYS,	
G. EMERSON.	
W. W. MORRIS, Dover, Del.	
T. C. DUNN, Newport, R. I.	
A. CLARK, New York.	
R. D. ARNOLD, Savannah, Ga.	

Philadelphia, June 5, 1847.

Dr. Hays, on presenting the report, stated that justice required some explanatory remarks should accompany it. The members of the convention, he observed, would not fail to recognize in parts of it, expressions with which they were familiar. On examining a great number of codes of ethics adopted by different societies in the United States, it was found they were all based on that by Dr. Percival, and that the phrases of this writer were preserved, to a considerable extent, in all of them. Believing that language that had been so often examined and adopted, must possess the greatest of merits for such a document as the present, clearness and precision, and having no ambition for the honors of authorship, the committee which prepared this code have followed a similar course, and have carefully preserved the words of Percival wherever they convey the precepts it is wished to inculcate. A few of the sections are in the words of the late Dr. Rush, and one or two sentences are from other writers. But in all cases wherever it was thought that the language could be made more explicit by changing a word, or even a part of a sentence, this has been unhesitatingly done; and thus there are but few sections which have not undergone some modification; while, for the language of many, and for the arrangement of the whole the committee must be held exclusively responsible.

On motion of Dr. L. P. Bush, of Delaware, the whole of the report, including Dr. Bell's introduction, was adopted.

Scrumptox.—The *North American Practitioner* has the following definition that will not be found in the dictionaries; "Scrumptox" is the English school boy's name for the severe form of impetigo occurring among the forwards of Rugby football teams. The "scrum," or "scrimmage," with its close commingling of heads, arms and legs in indiscriminate confusion, undoubtedly offers ideally favorable conditions for the communication of this disease, which is usually confined to the head and face, and often results in severe suppurative dermatitis, with glandular enlargement.

PUBLIC HEALTH.

Tuberculosis in Germany.—The Imperial Health Officer at Berlin is reported as stating that he has found evidence of tuberculosis in the body of every third person between the ages of 15 and 60 years examined by him.

Dangerous Spread of Cholera in Egypt.—Since the appearance of cholera at Damietta last October it has gradually been spreading, until now there are several localities where it is prevalent, and a panic exists at Alexandria and Cairo to such an extent that people are leaving in large numbers, even those in responsible positions. Eight of the twelve members of the Municipal Council have already fled from Alexandria. The *Semaine Médicale* of June 6 considers this flight of the residents of Egypt a serious menace for Europe, and urges the necessity of immediate quarantine measures. The gravity of the situation is shown by the fact that the authorities of Alexandria have at last commenced, since May 21, to add to their sanitary bulletins the statement that "Cholera exists in Egypt."

The Imperial Health Office of Germany.—According to the *Medical Press and Circular* considerable change in the personnel of the Institute have recently been effected. It is now just twenty years since the Institute was opened with two members—one for the medical and one for the veterinary department. Since then the number of members has steadily increased. There are now eight ordinary members, beside a number of associates. Another member is provided for, however, in next year's estimates, as the present staff is quite inadequate for the work demanded. The new member will undertake the department of public health, so far as it relates to injurious callings and adulteration of food stuffs prejudicial to health. He will also take in hand the testing of drugs in the interests of the new pharmacopœia. Dr. Josefo Brandl, Privat Docent in Munich, has been called to the new post and nominated an Imperial Regierungsrath. Dr. Brandl qualified in 1890, has studied chemistry, was several years assistant to Professor Tappeiner at the Pharmacological Institute, Munich, and is author of several contributions in his department of science.

Fixing Population by Resolution. After figuring its death rate for some eighteen months on a basis of 1,600,000 Chicago has resolved, through its city council, to cut down the rate by adding 150,000 to its population. The following is the text of a preamble and resolution to that effect adopted by that body at its meeting on the 22d inst.:

WHEREAS, A recent enumeration by the United States postal authorities shows that there are 202,511 habitations in the city of Chicago, exclusive of stores, office buildings, factories and other places not used for dwelling purposes: and

WHEREAS, The United States census authorities in 1890 found the average number of persons in each such habitation was 8.6; and

WHEREAS, It is desirable for certain municipal purposes that the population of the city be fixed and declared: therefore, it is hereby

Resolved, That the minimum population of the city of Chicago for the current fiscal year 1896 be held to be that determined by the above factors—that is to say, in round numbers, 1,750,000.

Probably this is as good a way as any to guess at what should be a matter of exact determination by a careful enumeration: but our whole system of census-taking, from the national inventory down to the census taken by the police force, is exasperatingly defective. No vital statistics based on such figures can possess any value or command any credence. Chicago, for example, on this officially resolved figure of population, will have a death rate of about 13.5 per thousand for the current year. The only thing which is absolutely certain concerning the city's mortality is that there have been a few less deaths so far this year than there were during the correspond-

ing period of last year. Between January and May, inclusive, in 1895 there were 10,436 deaths; this year there were 9,879 deaths. As deaths are reported with substantial accuracy, these figures may be accepted, but whether the deficit of 557 deaths this year is due to a loss of population or to more favorable seasonal conditions, is purely conjectural.

It is regrettable that our large cities do not adopt some such system of census taking as obtains in the large cities of Europe. Until this is done, our figures of population and death rates based thereon will continue to be looked at askance.

Epidemic of Smallpox in the Island of Guernsey in 1895.—In the *British Medical Journal* for May 2 Dr. Ernest L. Robinson of St. Peter Port treats of a variolous epidemic in that island, in 1894 to 1895. His testimony of the efficiency of vaccination is in a line with all other properly reported results where the health officers act promptly and energetically. He well says that to the great energy of the authorities in pushing vaccination is due the fact that the disease was stamped out in sixty days. It further appears from his report that not a single properly and timely revaccination was followed by the taking of the disease. And yet there are those among his and our fellow-citizens who ask us to throw away this grand prophylactic measure. He further says:

"Guernsey has been peculiarly free from smallpox for some time, there not having been an epidemic of this disease for about seventeen years. The epidemic began early in December, 1894, and the last case notified to the authorities appeared on Feb. 17, 1895. The disease was evidently imported from St. Malo, where a severe epidemic was raging at the time, by French people, as the first cases in the island were found among some women of that nationality, living in a low quarter of St. Peter Port. Before the disease had existed more than a few days, an ordinance was framed and published whereby compulsory vaccination was ordered and enforced in all parts of the island, the consequence being that by the middle of January, 1895, nearly half the population had been vaccinated or revaccinated. To the great energy of the authorities in enforcing these measures, with scarcely a delay of one day, is to be attributed the fact that the disease was eradicated in about two months from its first appearance, and that only forty-one persons out of a dense population of considerably over 35,000 were attacked. There were altogether forty-one cases; two of these were attended by a medical man who died shortly afterward, so that all that I can say about them is that they were both mild, and that both recovered. Of the remaining thirty-nine I have collected the following facts: Four deaths occurred; three of these victims were unvaccinated and the fourth (a prostitute worn out by various excesses) was only vaccinated some three days before the initial fever. Of the whole thirty-nine cases, twenty-four were unvaccinated (these latter including seven who were vaccinated during the period of incubation of the fever), and fifteen were vaccinated. I may add here that of the seven cases vaccinated during the period of incubation one died, as before mentioned, and the remaining six suffered mild attacks (discrete) only, showing that vaccination, even when performed so late in the day, is still very efficacious.

"There were seventeen cases of confluent smallpox, fifteen of these being unvaccinated, and two vaccinated, whose ages were respectively 34 and 15; the last had not even a trace of his old marks.

"There were twenty-two cases of discrete smallpox (all returned as mild cases), of which thirteen had been vaccinated in infancy. Of the remaining nine six had been vaccinated during the period of incubation of the fever, leaving only three absolutely unvaccinated.

"There was not a single case of a revaccinated person catching the disease with the exception of one person, who was revaccinated during the period of incubation.

"The ages of the thirteen mild cases among the vaccinated patients were 30, 24, 19, 35, 31, 4 (only two marks), 35, 30, 22, 18, 26, 13 (only two marks), 16. Thus only one of these was under 10 years of age, namely, a child of 4, with only two very indistinct marks."

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Louisiana: New Orleans, May 1 to 31, 25 deaths; June 6 to 13, 5 cases, 2 deaths; Shreveport, June 6 to 13, 6 cases.

SMALLPOX—FOREIGN.

Dublin, Ireland, May 31 to June 6, 1 case.
 Bologna, Italy, May 31 to June 6, 1 case.
 Bombay, India, May 12 to 19, 25 deaths.
 Calcutta, India, May 2 to 9, 3 deaths.
 Cardiff, Wales, May 31 to June 6, 1 case.
 Cerunna, Spain, May 16 to June 6, 5 deaths.
 Genoa, Italy, May 31 to June 6, 2 cases, 1 death.
 Gibraltar, May 24 to 31, 1 case.
 Licata, Italy, May 23 to 30, 3 deaths.
 Madrid, Spain, May 24 to June 2, 15 deaths.
 Montevideo, Uruguay, May 9 to 16, 3 cases.
 Moscow, Russia, May 9 to 23, 4 cases, 1 death.
 Naples, Italy, May 31 to June 6, 5 cases, 3 deaths.
 Osaka and Hiogo, May 2 to 24, 55 cases, 21 deaths.
 Palermo, Italy, May 23 to 30, 2 cases.
 Prague, Bohemia, May 23 to 30, 2 cases.
 St. Petersburg, Russia, May 23 to 30, 34 cases, 3 deaths.
 Southampton, England, May 30 to June 6, 1 case.
 Tuxpan, Mexico, May 23 to 30, 4 deaths.
 Warsaw, Russia, May 9 to 30, 4 deaths.
 Yokohama, Japan, May 8 to 15, 1 case.

CHOLERA.

Alexandria, Egypt, May 7 to 13, 125 deaths.
 Bombay, India, May 12 to 19, 16 deaths.
 Cairo, Egypt, May 7 to 13, 5 deaths.
 Calcutta, India, May 2 to 9, 177 deaths.

YELLOW FEVER.

Lagua la Grande, May 31 to June 6, 17 cases, 3 deaths.
 Havana, June 4 to 11, 17 cases, 9 deaths.

NECROLOGY.

J. F. POTTS, M.D., of consumption, at Detroit, Mich., June 8, aged 59 years. He was a student at Illinois College, Jacksonville, graduated from Union College, Schenectady, N. Y., then entered Jefferson Medical College Philadelphia, graduating there also. He served during the civil war in the Seventh Rhode Island cavalry.

CHARLES M. NES, M.D., at York, Pa., June 12, aged 69 years. Dr. Nes was one of the three commissioners appointed by General Grant to represent the State of Pennsylvania at the Vienna Exposition in 1873. He was the inventor of the Nes Silicon method of converting iron ore into steel, the discovery of which he made by noticing the peculiar action of electricity upon iron. On a visit to a patient who had been struck by lightning he noticed that the barrel of an old army musket which stood in a corner of the room and had felt the effects of the bolt, had been converted into a particularly high quality of steel. Acting upon the suggestion, he experimented with magnetic ore until the results obtained justified him in obtaining letters patent in the United States, Great Britain, France and Belgium.

EDWIN D. RAMSDALL, M.D. (Medical Department of the University of the City of New York, 1855), of pneumonia, at New York city, June 12, aged 66 years. He was a member of the Medical Society of the City and County of New York, which membership he held for twenty-five years. Until recently he was a member of the Academy of Medicine.

JOHN L. ROBINSON, M.D. (Harvard University Medical School, Boston, Mass., 1859), at Manchester, N. H., June 13, aged 61 years. He served during the war as a surgeon of the Eighth Massachusetts Volunteers, was a member of the Massachusetts and New Hampshire Medical Societies and one of the vice-presidents of Harvard Medical School Alumni Association.

MICHAEL H. MCGOVEN, M.D. (College of Physicians and Surgeons, Baltimore, Md., 1884), of apoplexy, at Pen Yan, N. Y., June 10, aged 38 years. Emer C. Hoover, M.D. (Medical College of Ohio, Cincinnati, 1878), of apoplexy, at Dayton, Ohio, June 13. — H. H. FERGUSON, M.D. (University of Louisville Medical Department, 1867), at Jeffersonville, Ind., June 15, aged 51 years. Egbert B. Henion, M.D. (College of Physicians and Surgeons, Baltimore, Md., 1882), at Sweden, N. Y., June 11. A. T. CLASON, M.D. (University Medical College, New York, 1886), at Danbury, Conn., June 16, aged 56 years. — Horace Hoyt, M.D. (University of Buffalo Medical Department, Buffalo, N. Y., 1848), at East Aurora, N. Y., June 17, aged 73 years.

MISCELLANY.

New York Polyclinic Medical School and Hospital.—Dr. W. W. Van Valzah has been elected Professor, and Dr. J. Douglas Nisbet, Adjunct-professor in the Department of General Medicine at the New York Polyclinic Medical School and Hospital. Their lectures will be devoted to "Diseases of the Blood and Digestive Organs."

Fraudulent "American" Potted Meats made in Europe.—According to the *Progrès Médical* of May 2, there are at Rotterdam and Antwerp large and important factories which import worn omnibus horses from London, and make them up into excellent potted meats, labeled as if they came from America and widely sold all over Europe. They dispose of 26,000 horses a year.

Acromegalia and Gigantism.—Brissaud considers these the same disease, the difference between them being merely a question of age. If it commences before the bones have attained their growth, they lengthen and produce the malformations known as gigantism, while they grow "cubically" in an adult, when it is called acromegalia—*Gazette Médicale de Paris*, May 16.

Decision that Venereal Disease is Sufficient Cause for Divorce.—The *Semaine Méd.* states that the Paris Court of Appeals recently decided that the fact of marrying before being cured of a venereal disease, and knowingly communicating it to the other party in the marriage, is sufficient cause alone to allow a divorce.

Yale Annual Address in Medicine.—The annual address in medicine of the Medical Department of Yale University was delivered by Ex-Col. Geo. E. Waring, Jr., June 23. In the evening a card reception to Col. Waring was given at the house of Prof. Charles A. Lindsley by the Medical Faculty of the University.

Anti-Streptococcus in Operating on a Diabetic Patient.—Boucheron recently removed a cataract from a patient, 70 years old, in an advanced stage of diabetes, complicated by the streptococcus affection, lymphangitis of the foot and limb. The operation was successful, the wound healing by first intention. He ascribes his success to the fact that he administered 20 grams of Marmorek's serum, which attenuated the streptococci, before he began operations.—*Gazette Médicale de Paris*, May 16.

Cerebral Hemorrhage in Whooping Cough.—A case is described in the *Deutsch. Med. Woch.* for April 23, in which the symptoms of cerebral hemorrhage, convulsions, hemiplegia, word-blindness, stupor, etc., suddenly appeared in the course of an attack of whooping cough. They gradually passed away after six days, until none were left by the end of three weeks. The writer adds that this is the eighth case on record of this complication, and in this case the patient, a lad of 8 years, had been instructed by his father to hold his hand over his mouth and nose to suppress the paroxysms, which may possibly have been the cause of the rupture of the blood vessel in the brain.

Five Months Fetus Developed in the Abdomen of a Young Man.—A strange case was reported at the meeting of the Académie de Médecine, May 5. A young man was operated upon for what was supposed to be a large abdominal tumor. It proved however to be a dermoid cyst, containing a female fetus as large as is usual at five months. The ovum in the cyst had probably lain latent until puberty or some traumatism had started it to grow. The young man did not long survive the operation, and died ignorant of the existence of a little sister in his supposed tumor. The *Jour. de Méd. de Paris*, for May 31, contains more details than are given in the *Bulletin* of the Académie.

Second Pan-American Medical Congress.—Dr. H. L. E. Johnson, Chairman of the Transportation Committee of the first Pan-American Medical Congress is arranging with the Passenger

Association for reduction in transportation for those who will attend the second Pan-American Medical Congress to be held in Mexico City in November next. The fare will in all probability be one and one-third rate on the certificate plan, but he hopes to secure a one fare rate for the round trip. An estimate will also be submitted for a special train, via Boston, New York, Philadelphia, Baltimore, Washington, Cincinnati, St. Louis, Laredo or Eagle Pass, to the City of Mexico and return. A full report will appear in the *JOURNAL* at an early date.

The Koch Institute of Berlin.—According to the *British Medical Journal*, May 16, the Koch Institute is not to be transferred to Dahlem after all. The Prussian government has decided to buy a plot of land close to the ground on which the new fourth Municipal Hospital is to be erected, in the See Strasse, and to build an enlarged and improved Koch Institute upon it. The decision, simple as it seems, has been arrived at only after long and wearisome negotiations. Now it is hoped that this knotty point once solved, the rebuilding and enlargement of the Charité Hospital will be attacked in earnest. The ground at present occupied by the Koch Institute is required for the hospital, but until the future of the Institute itself had been definitely settled, it was impossible to begin work. A new museum for the pathologic collections is urgently needed, as Virchow is terribly cramped in the Pathologic Institute. It is said that 1896 is to see this building begun, but delays have been so frequent in this Charité business that it is best not to prophesy.

One Death in 3,600 Cases.—The New York Institute for the Deaf and Dumb is creditably managed. For the last nine years one death has occurred, and this was from diphtheria contracted outside during vacation. Average number of pupils annually, 400; ages $2\frac{1}{2}$ to 18 years; average age, 8 years. This remarkable record is attributed to the diet of beef and mutton with few foods from the vegetable kingdom, as wheat, potatoes, etc. Obviously this is an institution for health as well as deaf mutes, and its methods are worth copying by those who have persons of like ages in charge. If there are other like cases they should be known. This report reflects great honor on all concerned, specially on Prof. Currier, the principal. Indeed, the Institute is a glory of New York!

Closing Scene in the Kitson Playfair Litigation.—A compromise has been reached in this case, and an appeal will not be undertaken by Dr. Playfair. On the day when the appeal was to have been moved, it was announced by the counsel for the defendant that the case had been settled on terms which had been agreed upon between the parties, and that therefore the court would not be troubled in the matter. The court assented to this course being taken, and thus the Kitson v. Playfair case reached its termination. No details were divulged respecting the terms of the settlement, and consequently upon this subject the natural curiosity of the public will have to remain unsatisfied. We are, however, in a position to state that the amount of the settlement agreed to was £9,200, to include costs incurred by Mrs. Kitson, and that of this sum £8,000 were to be invested for the benefit of Mrs. Kitson and her children.

King's Daughters' Hospital for Staunton, Va.—An act was passed at the 1895-6 session of the general assembly of Virginia incorporating the "King's Daughters' Hospital of Staunton, Va." It is empowered to maintain, at Staunton, a hospital for the medical and surgical aid, treatment and cure of persons who are sick, deformed or suffering from bodily injuries, and to instruct and train suitable persons in the duties of nurses for the sick. It is further provided that the corporation shall have full power to exclude such forms of disease or sickness as it may be deemed unsafe, improper or impracticable to admit to its hospital. It is also given power to collect fees for medical and surgical treatment and incidental expenses, and to

remit the same at its pleasure. The consolations of religion may be extended to the patients in the care of the corporation in whatever forms the patients may desire; but no influence shall be exerted within the hospital in the special interest of any particular sect or denomination.

Serum Treatment of Urinary Infection.—Albarran and Mosny produce a serum to combat urinary infection from the coli bacilli, by alternately vaccinating animals with the products of filtration and then infecting them with virulent cultures. This new alternate method produces a very active serum, while the animal retains his health and strength. An animal will survive a fatal injection of virulent culture if it is inoculated twenty-four hours before with one-twentieth cubic centimeter of this serum. More than this, the guinea pig, which is especially susceptible to urinary infection, will be protected against it, if one drop of the serum is added to a fatal dose of the culture. If two centigrams are injected two hours after a dose of the culture that kills in twelve hours, the animal does not succumb. Albarran and Mosny announced at the meeting of the Académie des Sciences, May 4, that this serum will not only effectually cure urinary infection, but will prevent it.—*Gaz. Méd. de Paris*, May 16.

Medico-Literary Notes.—The New York *Polyclinic* states that Empedocles of Agrigentum, may rank among the fathers of sanitation, inasmuch as he did, as long as 2500 years ago, make public an observation to the effect that the epidemic of puerperal fever had been caused by the influence of escaped sewer gas. *The Scalpel*, although a new claimant for the favor of the reading medical public, is really the *Provincial Medical Journal* under a new name. The latter journal departed its life at the end of last year, but the editor decided to raise out of its remains another journal, to which he has given the name of *The Scalpel*. The first number of the venture is before us. It appears in an attractive cover, and its contents are similar to those of its predecessor. The hand book of therapeutics, edited by Professors Penzoldt of Erlangen, and Stintzing of Jena, is making slow progress toward completion. Twenty-five fasciculi have now been issued, yet, owing to the unbusiness-like way in which the parts appear, only the first three volumes are as yet complete, and the conclusion of the third was contained in a fasciculus issued last month. In the prospectus the publisher expressed the hope that the whole work would be issued by the end of 1894, or, at the latest, by the spring of 1895.

John Arden or John of Arden on "Ye Goode Chirurgeon."—A very old code of ethics for surgeons is contained in the following citation that has been hunted up by the editor of the *Medical News*, who says: One of the interesting characters of the fourteenth century, was the sergeant surgeon of Edward III, in 1346, John of Arden. He gives a "Description of ye qualities which ought to be in ye surgeon that performeth any operation in chirurgery: First, that he be devout; secondlie, charitable to ye poor; thirdly, to use few words; fourthly, to avoid drunkenness; fifthly, to be chaste both in words and gesture, as well as to fear ye not; sixthly, not to undertake an incurable disease."

American Degrees Recognized in England.—A decision of the Queen's Bench Division of the High Court of Justice of England, according to a recent cablegram, lays down the dogma that an American practitioner having *bona fide* diploma is at liberty to pursue his calling unmolested so long as he does not claim to be a registered member of the British Medical Association. The decision, which was rendered by Justices Grantham and Collins, two of the most eminent judges of the High Court, was the finale of proceedings instituted against an American physician named Bridgewater, who was charged with having unlawfully, willfully and falsely represented himself to be a doctor of medicine, contrary to section 40 of the

medical act. It was shown that Dr. Bridgewater, in writing the words "M.D." after his name, invariably added "U. S. A.," and that hanging in his office were diplomas from New York and Philadelphia medical colleges of international reputation. The judgment of the court set forth that having used the letters "U. S. A." after his title there was no intent to defraud, and consequently no cause for prosecution. The Medical Defense Union is further mulcted in the costs of the litigation and the defendant's attorney's and other fees amounting to an aggregate of nearly \$4,000.

Quarantine for Convicts.—The 1895-6 general assembly of Virginia passed a law authorizing the governor, upon the application of the superintendent of the penitentiary, when requested in writing so to do by the physician at said institution, to have removed from the penitentiary any felon or prisoner serving a term of imprisonment who has contracted any contagious or infectious disease dangerous to the public health, to some place to be designated by the governor. When any such prisoner is so removed, he is to be safely kept and treated for such disease, and as soon as he recovers his health be returned to the penitentiary, unless his term of imprisonment has expired during his quarantine, in which event he shall be discharged, though not until all danger of his spreading contagion has passed. The judges of the county and corporation courts of the commonwealth are likewise authorized and empowered to have removed from the jails of their respective counties and cities, upon the application of the keeper of the jail, when requested so to do in writing by the physician doing the practice at the jail in question, all felons or prisoners serving terms of imprisonment in such jail and all persons who may be confined therein awaiting trial, who have contracted any contagious or infectious disease dangerous to the public health, to some place designated by the judge of the county or corporation court, where they shall be kept and cared for similarly to the provision made for the penitentiary prisoners.

To Protect the Children.—A law has been passed in Virginia which provides, among other things, that it shall be unlawful for any person, including in this term corporations, partnerships, companies, and associations, employing or having the custody of any child, willfully to cause or permit the life of such child to be endangered, or the health of such child to be injured, or willfully to cause or permit such child to be placed in such a situation that its life or health may be endangered, or to cause or permit such child to be overworked, cruelly beaten, tortured, tormented or mutilated. It is also made unlawful for any person having the care, custody, or control of any child under the age of fourteen years to sell, apprentice, give away, let, or hire out, or otherwise dispose of such child to any person in or for the occupation, service, or purpose of rope or wire walking, begging or peddling, or as a gymnast, contortionist, rider, or acrobat in any place whatsoever, or for any obscene, indecent or immoral purpose, exhibition, or practice whatsoever, or for or in any business, exhibition or vocation injurious to the health or morals or dangerous to the life or limb of such child, or cause, procure, encourage or permit any such child to engage therein.

A Definition of "Natural Labor." In the *British Medical Journal*, Dr. Robert R. Rentoul, of Liverpool, asserts that no clear notion is given in the laws regulating midwifery practice as to what the term "natural labor" means and includes. He proposes the following definition: "Labor at the ninth calendar month in a woman free from organic and functional disease of the heart, lungs, kidneys, brain, and other internal organs, and from all fever diseases; when there is no impediment in the maternal passage of either soft or hard nature to the passage of the child; when there is only one child in the womb; when the vertex of the child alone presents in either the first or second occipito anterior position; when labor is completed

within twelve hours from the commencement of labor; when a living child is born; when neither instrumental nor manual operations have been required; when the afterbirth comes away without the use of manual operation within twenty minutes after the birth of the child; when there is no laceration of any portion of the parturient structures; and when the mother does not die within thirty-one days after confinement, and when there is no puerperal fever."

Bicycle Racing Not Presumed Injurious.—The case of *Keeffe v. National Accident Society of New York*, decided by the appellate division of the supreme court of New York, April 14, 1896, was brought to recover on an accident policy of insurance for injuries sustained while riding in a bicycle race. The policy contained a provision that it should not extend to or cover injury resulting from voluntary over exertion, either voluntary or unnecessary exposure to danger, or to obvious risk of injury. The defendant contended that an injury sustained while riding in such a race was within the above exception, and moved for a nonsuit on that ground. The trial court denied the motion, and, on that subject, submitted to the jury the question whether the plaintiff was injured by his voluntarily or unnecessarily exposing himself to danger, or to the obvious risk of injury. This was, the appellate court thinks, a correct disposition of the question raised. It can not be said, as a matter of law, declares the court, that the plaintiff was overexerting himself, nor that he voluntarily exposed himself to danger by entering into the race. Different and equally intelligent and unbiased men might fairly differ in opinion as to whether or not, by taking part in such a race, any risk of injury was necessarily incurred, and therefore the trial judge was right in leaving the decision of that question to the jury.

An American Physician Highly Honored in China.—From the *Medical News* we learn that "Dr. Boudinot Currie Atterbury, medical missionary of the Presbyterian church to China, has been honored by the Emperor of China with the Imperial Order of the Double Dragon, Second Degree, a distinction never before conferred on any foreigner, excepting, perhaps, the ruler of some friendly power. This mark is in recognition of the notable services rendered by the American physician in connection with the work of the Red Cross Society, during the late war. Dr. Atterbury was born in New York City, and comes of a family long prominent in New York. He studied at Yale College, and took his medical course in this city, under the direction of Dr. Frank H. Hamilton. After he was graduated in medicine from Bellevue Hospital Medical College, of the class of 1877, he went to China under the auspices of the Presbyterian Board, and was assigned to missionary duty in the city of Peking. He there assisted in the establishment of the Ah Ting Hospital. While there, his work was brought to the attention of the emperor and the royal family. He afterward went to Tientsin, where he is at present."

Metals in the Blood.—Kobert has been studying the rôle played by the red blood corpuscles when neutral metals are injected. He finds sixteen metals that combine with the hemoglobin: Zinc, iron, silver, lead, mercury, etc. They form a metal-hemoglobin which must be regarded as a chemie entity. Injections of the bichlorides of different metals into the undissolved corpuscles, either in or outside of the body, lead to the formation of these metal-hemoglobins, but the saturation of the corpuscles in the body is not so great as outside. Acute iron poisoning is therefore to be considered as an "internal choking" resulting from the transformation of the hemoglobin of the blood into this metallic hemoglobin. Death follows intravenous Hg. injections long before the hemoglobin becomes saturated with the metal, but as there is already more or less of this "internal choking" in advanced life, transfusions of human blood should be made in cases of intoxication, or at least transfusions of alkalies, carbonate or bicarbonate of sodium, to realkalize the blood, accompanied by inhalations of pure oxygen.—*Centralblatt f. Chirurgie*, April 11.

Hospital Notes.

The United States Marine Hospital at Chicago, Ill., is to have an addition of an operating amphitheater, with all the latest appliances for aseptic work. The structure will cost \$6,970.

Bangor General Hospital, Bangor, Maine. At a meeting of the hospital corporation June 15 it was voted to change the name of the institution to the Eastern Maine General Hospital. The following officers were elected for the ensuing year: President, Charles Hamlin; Vice-President, Edward Stetson; Secretary, Charles H. Bartlett; Treasurer, Charles D. Crosby.

Presbyterian Hospital, New York City.—The management of the Presbyterian Hospital has issued a "Medical and Surgical" report under the editorship of Andrew J. McCosh, M.D., and Walter B. James, M.D. In the preface to Vol. 1, January, 1896, the commendable object of the publication is stated as follows: The management of the Presbyterian Hospital issues this, its first medical and surgical report, believing that a permanent record should be made of the valuable and interesting scientific material that is found in the hospital. The first duty of a hospital is to care for the sick. Its next duty is to advance in every possible way the knowledge of the nature and treatment of disease. It is proposed that this shall be the first of a series of reports to be published annually.

In addition to tabular statements of diseases and injuries treated it contains full reports of unusual and interesting cases. Dr. Francis P. Kennicut reports a case of "General Tubercular Infection, including the Testes, etc., in Child 2½ years old." F. Alden Brown reports two successful cases of amputation at the hip joint. "Tuberculous osteo-arthritis of hip. Amputation at the hip-joint by a new method, through an antero-external incision. T. D., age 27. Female. Preparation for amputation consisted in a brief massage of the leg and thigh while held perpendicularly. At the same time one jaw of a specially made clamp was passed through the existing incision, guided by the finger, under the sartorius and under the femoral vessels close to Poupart's ligament, the other jaw being outside the wound and bearing upon the cutaneous surface overlying the vessels. As the clamp was moderately tightened and the limb lowered, pulsation of the femoral below the clamp could not be felt by the finger in the wound. The handle of clamp rested upon the abdomen, where it lay parallel with the flare of the pelvic brim.

"The application of the clamp to the vessels was a simpler matter than I anticipated. It required but a moment or two to force the finger under the sartorius and under the sheath of the vessels as it lay upon the psoas, and through this short space, along the upper side of the finger, was slipped one blade of the clamp, the tip of which was gloved with rubber tubing, a possibly unnecessary precaution against injury to the vessels.

"It was presumed that the anterior crural nerve would lie just to the outer side of the clamp compression, and in the same fenestrum of the instrument as that surrounding the sartorius. The patient's pelvis was now brought to the end of the table. The left leg was supported by an assistant, while the right thigh was flexed upon the pelvis and secured to the abdomen and table. The existing incision was extended along the outer border of the rectus downward to the bone, and through this deep incision the remaining attachments to the joint and femur were mainly stripped off. A circular skin cuff was cut and turned back. The femoral clamp was tightened one point before severing the muscles with a circular sweep to the bone. Some of the small branches of the sciatic system required the application of pressure forceps, but the femoral vessels and their branches were absolutely dry on the proximal side. It remained only to turn backward the open muscular cuff, raise through it the femur, and sever the posterior part of the capsular ligament, when the head of the bone was turned outward by my assistant and the round ligament cut. The femoral was ligated with silk, all outer vessels with catgut. Gradual loosening of the femoral clamp by stages permitted an excellent opportunity of seizing the bleeding points in regular order of their importance, and the clamp afforded a simple method of quickly starting or closing the blood current in the main channel.

"The rather extensive muscular portions concerned in the abscesses and sinuses had been cut away with scissors before ligation of the vessels. The diseased portion of the acetabulum was curetted and the wound flaps united by interrupted silk-

worm gut, then more accurately adjusted with a continuous suture of fine black silk. Drainage by iodoform gauze was provided at the uppermost part of the wound, and through the large sinus formerly behind the trochanter. As all preparation had been made to utilize saline venous infusion at some time during the operation, one and a half liters were now thrown into the median cephalic vein by Dr. Hartwell while the wound was being sutured. The beneficial effect of this infusion was at once manifest and the patient left the table with a fuller and slower pulse than she had had since admission to the hospital."

Practical Notes.

The Topic Action of Salacetol.—Ricchetti announced in 1894 that salacetol has the advantage over other combinations of salicylic acid, that it is a fine antiseptic for the intestinal canal without occasioning any toxic effects, even when taken into the stomach in large doses. Also that it has no effect on the soluble ferments, while it retards and arrests the figured ferments, and that it prevents the development of the cholera and typhoid micro-organisms and also of the coli bacillus. Mosso of Genoa has been recently studying its effect in local applications, with equally favorable results. He finds that applied externally, the temperature of the body and a slightly alkaline liquid, favor its separation into its two components, salicylic acid and acetol, and it produces immediately its antiseptic effect without irritating the tissues. The same amount by weight contains more salicylic acid than salol. It does not require, like salol, several hours to produce its effect; and the products of its separation into its elements are not toxic. Mosso experimented with it in the form of a powder, a salve (20 grams salacetol to 100 grams ung. sim. or vaselin). And in liquid form (4 grams salacetol in 50 grams water and glycerin).—*Gazzetta degli Ospedali e delle Cliniche*, April 14.

Injections of Hot Water in the Treatment of Chronic Diarrhea.—Pollatschek of Carlsbad, has found that small, repeated injections of hot water are very beneficial in the treatment of chronic diarrhea. He uses only enough water at 104 to 109 degrees as will be retained and absorbed by the intestines, beginning with 100 grams. The effect is similar to that produced in vaginal and uterine troubles, relieving the congestion and calming the nerves of that region. The hot water also stimulates the peripheral centers that control the peristaltic movements of the bowels, and chronic diarrhea is often permanently cured by this method. Helles, of Lyons, has also recently published a paper on this subject. He recommends the decubitus dorsal position to retain the injection, and uses much hotter water, from 113 to 130 degrees.—*Semaine Médicale*, May 13, and *Journ. de Méd. et de Chir.*, May 25.

Influence of Hot and Cold Baths on the Chemic Changes of the Blood and Urine.—Strasser announces that cold baths seem to increase the amount of alkali in the blood and diminish the amount of acidity in the urine. Hot baths, on the other hand, seem to increase the amount of acid in the urine, while diminishing the amount of alkali in the blood. This result is the more surprising as both hot and cold baths increase the amount of chemic changes. He explains it by the fact that hot baths produce rather an organic dissociation than an oxidation, while cold baths produce the opposite effect. Kapper has shown that the urine becoming alkaline with a vegetable diet will become acid under the influence of cold baths. Strasser ascribes the alkalinity of the urine to the excess of alkaline carbonates, and as cold baths increase the elimination of carbonic acid through the lungs and the skin, the urine thus ceases to be alkaline.—*Le Semaine Médicale*, May 13.

Diffuse Multiple Neuritis in Secondary Stage of Syphilis.—The patient was a young butcher with pronounced chancres and eruptions; eyebrows, mustache and beard dropping out, complete atrophy of many of the muscles and partial paralysis, with absolute inability to walk or move the extremities. Feet turned in like a paralytic. No pain was felt spontaneously, but pressure on the calf was very painful. There was no

sensibility to a prick or touch on the foot or right limb, while it remained normal to heat. The vesical and rectal sphincters were normal in their action. This last fact and the marked predominance of the paralysis in the extremities, with the differences in sensibility, all spoke against myelitis. The symptoms were those of Leyden's peripheral multiple neuritis, motor form, and its etiology was determined by the presence of the syphilitic symptoms. The treatment was a weekly injection for three months of thymol, and acetate of mercury, and the patient was restored to comparative health. Essential lesions of the peripheral nervous system, due to syphilis, are quite rare. In most cases they are limited to certain localities, sciatic, facial, &c. There are only two descriptions on record that coincide with this case, and they were attributed to myelitis.—*Annales de Derm. et de Syph.*, April.

Oxygen Antidotal to the Sequelae of Etherization.—The *American Therapist*, May, quotes Dr. Theophilus Parvin as being a convert to the views of Professor Landau, of Berlin, as to the use of oxygen after ether anesthesia. Dr. Parvin further observes that Landau is one of the few Berlin operators who prefers ether to chloroform as an anesthetic: and he has found by a very large experience, that as soon as the operation is ended, if the patient immediately inhales oxygen freely for a few minutes, she does not subsequently suffer from headache or nausea and vomiting. The immediate effects of inhaling oxygen are: The dusky hue of the face disappears, and the pulse becomes fuller and slower: there is, too, a more rapid recovery of consciousness. He had many opportunities of witnessing these results at Dr. Landau's hospital. The day subsequent to operations, Dr. Parvin several times visited these patients, at the doctor's request, asking them as to the freedom from vomiting and pain, and the invariable reply was that they had neither. The *Medical and Surgical Reporter* is the source of the *Therapist's* quotation.

Migraine.—The legion of proposed remedies for the cure of migraine, indicate the difficulty of hitting upon a rational treatment. Seguin advises as a prophylactic treatment, Indian hemp at the dose of one-fifth grain given three times a day in pills, associated with iron and arsenic; it should be continued for some time. The best treatment for the attack, when depending on nervous causes, is cafein and antipyrin, cafein 2 grains, antipyrin 10 grains, to be renewed in an hour if necessary. Salicylate of soda at the dose of $\frac{1}{2}$ dram is almost a specific where the headache is derived from a gouty or rheumatic diathesis. Bromid of potassium was believed by Charcot to be the remedy, *par excellence*, of the ophthalmic form. A writer in the *Press and Circular* closes up an article on this subject with the following hint: Many medical men prescribe with success exalgin as follows:

R	Exalgin	06
	Rum	30
	Syrup	30
	Water	120

Misce. A tablespoonful three times a day.

Tannalbin.—This name has been given by Gottlieb in an article in the *Deutsche Medicinische Wochenschrift* to an albuminate of tannin rendered insoluble in the gastric juices by being heated for five or six hours at a temperature of between 100 and 120 degrees C., and yet slowly soluble in the alkaline intestinal secretions. The preparation appears as a pale yellow powder, quite tasteless, and containing about 50 per cent. of tannic acid. Its clinical utility has been tested by Engel, who employed it in forty cases of various forms of intestinal disturbance, catarrhal and diarrheal conditions, and found it to be an efficient intestinal astringent, possessing the usefulness of a tannic acid preparation without any ulterior influence upon the functions of the stomach. The drug was administered in powder form to adults in doses of $7\frac{1}{2}$ grains, three or four times a day, and preferably at intervals of an hour or two.

Value of Silver as an Antiseptic.—It may be some consolation to the silver men to learn that science has recently found an important use for silver, as announced at the Berlin "Chirurgencongress" by Crede, of Dresden. If a plate of metal is placed on a culture of staphylococcus aureus, a sterile zone soon forms around it, while the metal itself is affected by the secretions of the microbes, which produce lactic acid, forming a lactate of the metal. Thallium is the most powerful in this respect, and silver next, but as the lactates of thallium and of silver are very poisonous, Crede experimented chiefly with the carbonate of silver, impregnating with it silks, catgut and drains, and using it on gauze in a fine powder or in leaf sheets. It proved exceedingly effective as an antiseptic for wounds where a prolonged action was desired, while never causing pain nor irritating the tissues. He found it still antiseptic even after remaining on a wound eight days. He has also administered it hypodermically in five cases of acute infection, such as erysipelas, with success and no unpleasant results. In one case the solution contained one gram of lactate of silver. He speaks from seven months' experience.—*Semaine Médicale*, June 3.

Lithiasis of the Gall Bladder.—The last five meetings of the Paris Société de Chirurgie have been devoted to this subject, and have brought out descriptions of 42 new cases. We note in the reports published in the Paris medical journals for May, that one point to remember in differentiating lithiasis of the gall bladder from a wandering kidney, is that when pressed with the finger it stays, while the latter slips away from under the finger. The most difficult diagnosis of all is when these two are combined, or when the gall bladder is forced so low down by the enlarged liver that it is mistaken for an appendicitis. Tuffier described one case operated upon which proved to be an old extra-uterine pregnancy, the more remarkable as the patient had recently passed through a normal child birth. In Routier's eight cases hepatic colic was present, but this was not the case with most of the rest. In regard to the operation, that known as "Ideal Cholecystostomy" was generally denounced, although two very successful cases were reported, with removal of 233 gallstones in one. Tuffier prefers cholecystectomy when it is easily performed, when the reservoir is not infected and the bile duct is permeable. In short, he extirpates in good cases, and performs cholecystostomy in bad cases, which seemed to be the general practice. Schwarz insists upon the importance of a double ligature of the pedicle and the use of the thermo-cautery. In some cases a correct diagnosis was impossible at first, until the affection had progressed further. The fistula left afterward often seems to benefit the general health, and can be closed later at any time, and often heals of itself. When the pedicle can stand ligating, draining is not necessary. In removing the gall bladder, it is easy to avoid injury to the parenchyma of the liver, by cutting it away with small snips of the scissors in the fibrous tissue enclosing the bladder, rather than in the tissue of the liver. It does not bleed, and leaves a bed of fibrous tissue under the liver which can be closed up by fastening together the two lips of fibrous tissue adhering to the liver.

Louisville.

HOSPITAL COLLEGE OF MEDICINE AND DENTISTRY.—The joint commencement of these institutions was held at the same place on the 18th inst., the graduating classes wearing caps and gowns. There were thirty-one graduates of the dental department and forty-nine of the medical. Addresses were made on behalf of the faculties by Prof. P. Richard Taylor, Dr. Peaybody, Dr. Jno. A. Larrabee, President of the College, and Col. Bennett H. Young on behalf of the Board of Censors.

ALUMNI.—The annual meeting of the Alumni of the Hospital College of Medicine was held in this city on the 18th inst. about 100 members being present. Dr. E. C. Underwood is president, Dr. T. E. Converse, vice-president and Dr. Philip F. Barbour, secretary.

MEDICO-CHIRURGICAL SOCIETY.—Dr. S. G. Dabney was recently elected president of this society and Dr. Thos. Hunt

Stucky was made secretary. The society was the guest of Dr. Lewis S. McMurtry at the Kenton Club on the 19th, the title of the essayist's paper being "The Development of the Modern Aseptic Surgical Technique."

HEALTH OFFICER'S REPORT.—For the past week there have been sixty-one deaths and six stillbirths. Consumption caused eleven, and only two of the deaths occurred at the City Hospital.

PHARMACISTS.—The State Pharmaceutical Society held its annual session at Estill Springs, and the following officers were elected for the coming year: President, J. M. McFarland, Henderson; vice-president, J. C. Hearn; secretary, J. W. Gayle, Frankfort; treasurer, C. S. Morris, Louisville.

Washington.

WEEKLY REPORT OF THE HEALTH OFFICER.—The report of the Health Department for the week ended June 13, is as follows: Number of deaths (stillbirths not included) 91; death rate per 1,000 per annum 17.2; death rate per 1,000 per annum corresponding week last year 13.7. There were 38 deaths of children under 5 years of age, of which 8 were of a diarrheal nature.

MEDICAL SOCIETY.—At the meeting of the Society held on the 3d inst., Dr. Belt reported cases of sponge grafting in socket for artificial eyes and presented patient showing results. On the 10th inst. Dr. Kerr reported two cases of the rupture of the bladder.

WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.—At the meeting held on the 5th inst., Dr. E. L. Tompkins read a comprehensive paper on chorea. A full discussion followed. At the meeting held on the 19th inst., Dr. Fry read a paper entitled "Manual Rectification of Faulty Head Presentations." The next meeting will take place in October for the election of officers and presidential address.

ARTESIAN WELLS FOR THE DISTRICT.—The District appropriation bill contains an item of \$4,000 for the construction of fifteen wells which will consist of a six-inch casing driven to a depth of about three hundred and fifty feet through the solid rock formation. The driving of these wells will mark the beginning of a new drinking water supply for Washington, for as soon as they are established all of the shallow wells will be done away with.

BOARD OF MEDICAL EXAMINERS APPOINTED.—The Commissioners under the recent law have appointed the following physicians to constitute the Board of Medical Examiners for the District of Columbia: For the regular school, Drs. C. H. A. Kleinschmidt, G. Wythe Cook, J. S. McLain, G. C. Ober and C. B. Purvis (colored). For the homeopathic school Drs. J. B. G. Custiss, S. S. Stearns, W. R. King, Z. B. Babbitt and T. L. McDonald. For the eclectic school, Drs. Robinson, Geddis, Julihn, Heiser and one yet to be named.

Philadelphia.

UNIVERSITY OF PENNSYLVANIA.—Last week was commencement week at the University of Pennsylvania. The exercises of the 140th annual commencement marked the 156th year of the university's existence. The standard of scholarship has been raised in all the departments this year, and serious complaint was made, especially by members of the Dental class of the severity of the examinations. The standard of the entrance examinations will also be higher in future and, at each session, will be gradually raised until the fall of 1899, when it is expected that a degree in arts, or its equivalent, will be required of every matriculant in the medical department. It is to be remarked that this department is becoming more closely connected with the other departments of the University than it was formerly, an illustration being furnished by the fact that the salaries of the members of the medical faculty are fixed and are independent of the income received from medical students and unaffected by the size of the class. A pleasant

feature of the commencement week was what was called "Alumni Day," when there was a general meeting of the alumni of all departments and the annual meeting of the general Alumni Society. The latter was held at noon, June 10, at Houston Hall and was followed by a lunch in the library. A reception was tendered to the provost, Dr. Harrison, in the afternoon and banquets by the alumni of the medical and dental departments were held in the evening. The commencement or the medical department was held June 11 at noon, as usual at the Academy of Music, the degrees being conferred upon eighty-eight candidates.

A NEW DEAN AT THE MEDICO-CHIRURGICAL COLLEGE.—Dr. Isaac Ott has been elected Dean of the Medico-Chirurgical College as the successor of Dr. Laplace, who resigned in order to devote his whole time to the duties of the chair of surgery. Dr. Ott is also professor of physiology in the Medico-Chirurgical, a position which during the last two sessions he has filled very acceptably to the students, among whom he is very popular. He has recently been elected consulting neurologist to the State Hospital for the Insane at Norristown.

PHILADELPHIA HOSPITAL.—The results of the examinations for the positions of resident physician at the Philadelphia Hospital have been made public. The examining board consisted of Drs. H. C. Chapman, J. M. Anders and Judson A. Daland. There were sixteen vacancies, which were filled by the Board of Charities in accordance with the recommendation of the examining board, by the election of six University men, five Jefferson men and five from the Medico-Chirurgical.

FRESH AIR CHARITY FOR CHILDREN.—One of the most useful of the medical charities of the city is the Sanitarium at Red Bank, on the Delaware River several miles below the city, which opened on June 4 for its eighteenth season. During the seventeen years, of which careful records have been kept, 1,409,402 persons, mostly children, have been carried to and from the sanitarium and without a single serious accident. Last year the total number of admissions were 174,481. The association owns two commodious steamboats and an enclosed park of over eighty acres, with administration buildings, temporary hospital and other appropriate structures, the latest of which is the Simon Muhr Memorial Building, which has just been opened and which will be devoted to the preparation of diet. The sanitarium is especially designed to afford opportunity to poor children during the hot weather to escape from the streets and alleys of the city and enjoy a trip on the river and a day at the grounds where an abundant supply of milk, soup and sandwiches are provided, with tea and coffee for the caretakers. Tickets are distributed among physicians, who give them to those deemed worthy. Especial care is taken that children suffering with contagious diseases shall not be taken.

SMALLPOX AND VACCINATION IN THE PUBLIC SCHOOLS.—The Board of Health of the city has made the rule absolute that no child shall be permitted to enter the public schools without having been vaccinated, or protected by a previous attack of smallpox. They have further notified all private schools and also the Sunday schools that they must comply with this rule and refuse to receive any pupil who is not provided with a certificate of vaccination. The latter requirement has been pronounced impracticable, although many of the persons most concerned by it entirely approve of it in principle.

THE AMERICAN NEUROLOGICAL ASSOCIATION MEETING.—The twenty-third annual meeting of the American Neurological Association assembled June 3 at the College of Physicians and during this and two following days held very profitable meetings under the direction of Dr. F. X. Dercum, president; Drs. C. E. Riggs of St. Paul, and G. J. Preston of Baltimore, vice-presidents, and Dr. G. M. Hammond of New York, secretary and treasurer. The next session will be held at Washington, with the Congress of American Physicians. Dr. M. A. Starr

of New York was elected president: Drs. H. R. Stedman of Boston and H. S. Upson of Cleveland, vice-presidents, and Dr. Hammond was re-elected secretary. Receptions were given by the Philadelphia Neurological Society at the Philadelphia Medical Club which were largely attended.

THE COUNTY MEDICAL SOCIETY.—At the meeting of the Philadelphia County Medical Society, held on the 11th inst., Dr. Ernest Laplace read a paper on the "Surgical Treatment of Insanity," in which he reported four cases of acute insanity with delusions, which had come under his notice. They all suffered with headache and had histories of injuries to the head, although there was no evidence of injury sufficiently severe to produce fracture having been inflicted. In each of these four cases he had used the trephine and in three had made a linear craniectomy along the coronal suture, or in front of it, to the extent of some three inches, and had introduced a flat instrument to separate the dura mater from the skull over both cerebral hemispheres as far back as he could go. In the last case, that of a man of 26 years of age, who for eleven months had had melancholia and delusions of persecution, and who was steadily getting worse, Dr. Laplace operated as above stated, and noted the fact that there was considerable hemorrhage during the operation. As soon as the operation was over, the patient was found to be absolutely sane and free from all delusions and even without remembrance of those which had annoyed him for months. He had remained perfectly well since and was presented at the meeting although the operation had only been performed May 29. There was a recent scar several inches in length on the vertex, wound having entirely healed. The patient had no more headache and was cheerful and apparently perfectly well. Dr. Laplace said that the free hemorrhage in this case might have brought about the result, but he gave most of the credit to the relief of pressure by the operation. It was certainly remarkable that these were the only cases of insanity that he had been called upon to treat and that in each case such good results should be obtained by opening the skull. At the same meeting, Dr. R. Meade Bolton, Superintendent of the Bacteriological Laboratory of the City Board of Health, reported the results of the examination of cultures from cases of suspected diphtheria from May 30, 1895, to June 1, 1896. The total number of examinations were 3,363, of which 1,421 were of primary cases and 1,942 secondary. A diagnosis was given of diphtheria in 557 cases and it was confirmed by the attending physician in 507 cases, or in 90.2 per cent. The diagnosis of not diphtheria was given in 148 cases and confirmed in 108. The total number in which the diagnoses was given by the department was 705 and it was confirmed in 615 cases, or in 86.4 per cent. This was regarded as a very satisfactory result for the first year's work of the new department, which under Dr. Bolton's able management is working harmoniously with the other departments and the profession. Dr. Edward Jackson read a paper on "The Profession, the Optician and the Public," in which he defended the view that the examination of the eye and the measurement of refraction can only be done properly by those who have a medical training and special experience. The optician represents the pharmacist and should confine himself to filling the prescriptions and should not assume the responsibilities of the ophthalmologic physician. A report of a case of varicella gangrenosa was read by Dr. J. P. Crozer Griffith, who also exhibited photographs of the case, which terminated fatally.

COLLEGE OF PHYSICIANS. At the June meeting of the College of Physicians, Dr. Joseph Leidy read a "Note on Infantile Scurvy" and reported several cases. The symptoms were liable to be mistaken for rheumatism. He believed that sterilized milk was a potent cause of this form of nutritive disorder which is generally promptly ameliorated by an improved diet. Dr. Oscar H. Allis read a paper entitled: "The Mechanism of the Dislocation of the Shoulder and Hip Deduced from Their Accidental Restorations," and presented specimens. The following were elected to Associate Fellowship at this meeting: Sir George Murray Humphry, Bart., Cambridge, England;

Professor Jaccoud, Paris, France; Dr. George M. Sternberg, U. S. A., Washington, D. C.; Dr. Phineas Sanborn Conner, Cincinnati, Ohio; Dr. L. McLane Tiffany, Baltimore, Md.; Dr. William T. Lusk, New York.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from June 13 to June 19, 1896.

Capt. W. Fitzhugh Carter, Asst. Surgeon, is granted leave of absence for one month, with permission to apply for an extension of one month.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending June 20, 1896.

Surgeon R. Whiting, detached from the "Monterey," ordered home and granted three months' leave.

Surgeon C. T. Hibbert, detached from the "Bennington" and ordered to the "Independence."

Surgeon H. T. Percy, detached from board of examiners, Washington, D. C., July 1, and ordered to the "Monterey."

Surgeon W. A. McClurg, ordered as member of medical examining board, Washington, D. C.

P. A. Surgeon J. W. Baker, detached from board of examiners, New York, June 22, and ordered to the "Bennington."

P. A. Surgeon C. F. Stokes, ordered as recorder of medical examining board, New York, June 22.

Surgeon A. C. Russell, detached from board of medical examiners, New York, July 5, and granted leave until August 7, with permission to go abroad.

Asst. Surgeon M. K. Johnson, detached from the "Franklin" and ordered to the "New York."

Asst. Surgeon F. C. Cook, detached from the "New York" and ordered to treatment at naval hospital, New York.

Asst. Surgeons W. N. Wheeler and R. S. Blakeman, ordered to instruction at naval laboratory, New York.

P. A. Surgeon J. W. Baker, ordered to delay reporting until July 18.

Change of Address.

Bell, G. Franklin, from Williamsport to Newberry, Pa.
Burroughs, Sam. R., from Raymond to Buffalo, Texas.
Bonner, C. A., from 33 S. High St. to 28 S. Perry St., Dayton, Ohio.
Bulkley, J. W., from 805 12th St. N.W. to 1723 N St. N.W., Washington.
Bassett, L. A., from Chicago to Jefferson, Iowa.
Corley, H. N., from St. Louis to St. Paul, Mo.
Dobson, S. J., from Jefferson to Edna, Kan.
Durant, G., from New York, N. Y., to Branford, Conn.
DeHart, J. N., from Brooklyn to Round Lake, N. Y.
Edmondson, Geo. J., from Chicago to Moroa, Ill.
Fortier, J. J., from 123 Blue Island Ave. to 318 New Era Bldg., Chicago.
Givens, Jno. W., from Baltimore, Md., to Los Angeles, Cal.
Hobday, W. A., from Biwabik to Halted, Minn.
Jordan, J. D., from Chicago to Madisonville, Texas.
Ketcham, L. Y., from San Diego to Esccondido, Cal.
Kimball, H. H., from Medical to Dayton Bldg., Minneapolis, Minn.
Maxey, S. B., from St. Louis, Mo., to Sherman, Texas.
Marr, W. L., from 61 N. State St. to 5451 Lake Ave., Chicago.
Mulholland, J. F., from Jordan, Minn., to Manitowoc, Wis.
Paine, H. M., from West Newton, Mass., to 67 N. Forsyth St. Atlanta, Ga.
Quigley, J. M., from Portland, Ore., to 41 6th St., San Francisco, Cal.
Rubuck, S. H., from Chicago to Lyle, Minn.
Star, J. W., from Liberty Center to Lacona, Iowa.
Yemans, H. W., from New York, N. Y., to 307 Walnut St., Philadelphia.

INDEX TO VOLUME XXVI.

	PAGE.		PAGE.		PAGE.
ABDOMINAL ailments, cases bearing upon the question of operative interference in	1206	Anemonin, physiologic effect of	382	Asepsis in military surgery, some remarks about	167, 226
pregnancy, rupture of sac and death of fetus in, at full term	369	Anesthesia, effect of, upon the temperature the urine after	1124	Aseptic labor, how to secure	113
Abortion	442	Anesthetics, a safe method to administer, with oxygen	1211	Ashmead, Albert S. A leprosy congress	1138
circumstantial evidence of	44	and ruptures in Scandinavian countries, statistics of	434	Dr. Albert S. Introduction of leprosy into Nova Scotia and the province of New Brunswick	202
criminal	257	should not require administration of	443	Dr. Albert S. Leprosy in the Argentine Republic	665
legalized	388	Aneurysm, an unusual case of	498	Dr. Albert S. Racial degeneracy	993
Aberdeen new epidemic hospital	791	Anger, the physiologic effects of the indulgence in	781	Association badge	789
Absorption, pressure necessary in	495	Anglo-neurotic edema	30	of American Medical Colleges	292, 769, 827
Acetanilid and bismuth, poisoning by	788	Animal therapeutics, the present status of	528	Astasia-abasia, a case of	966
availability of, in country practice	144	Animals, to prevent cruelty to	198	Asthma, spasmodic, caused by aortic aneurysm	69
poisoning by	239	Anthelmintic remedies	694	Athletic exhibitions, dangerous, should be restricted	1036
Acetylene gas	743	Anthropometric or Bertillon system of identification, proposed adoption of, in New York	846	Atlanta, railroad rates to	442
Achilles Rose, a recruit for	1192	Anti-alcoholic teaching in New York public schools	791	Aural masseur, an	277
Acne, treatment of	1245	Anti-phthisis, therapeutic effect of	740	polypi, surgical treatment of	119
Acoustic sensations, effect of, on the pulse and respiration	1144	Antipyretics, for and against	446	Autophakoscopy, the	290
Acquittal of a physician unjustly accused	944	external	445	Autoscopy of the larynx and of the trachea	265
Acromegalia and gigantism	1278	Antipyrin and quinin, a new reaction for	446		
Actinomycosis in the lungs	294	as an anesthetic for the bladder	397	ASSOCIATION NEWS.	
Addison's disease and adrenal extract	1013	Anti-streptococcus in a diabetic patient	1278	Address of welcome on behalf of the local profession	1030
Adenocarcinoma of the stomach	581	Antithermic analgesics, the six groups of	797	of Welcome on behalf of the citizens of Atlanta	1032
Adenoid vegetations, relation of, to irregularities of the teeth	323	Antiseptic tablet for nasal wash	123	Annual report of the Board of Trustees for eight months ending Dec. 31, 1895	984
vegetations, discussion of treatment of	1197	Antiseptics, purgatives and milk as	344	Atlanta physicians preparing for the meeting	286
Adenoma sebaceum	219	Anti-tetanus serum, a new	1241	Excursion rates to Atlanta	689
Adler, Dr. Lewis H. Treatment of cancer of the rectum	1152	Antitoxic property of the blood of animals	1093	Jenner centennial celebration	93
Adulteration, ignorance of, no defense	941	Antitoxin, death from	687	Local committee of arrangements	540
of foods and drugs in California, to prevent	1188	discussion of fatality following the use of	996	Notice to the Ophthalmological Section	891
Africa, tropical, a white race native to	744	higher grades of, for diphtheria	742	Official report of the forty-seventh annual meeting	982
Airol, new substitute for Iodoform	596	injection of	1088	Permanent location of Journal	988
Alabama's embalming law	945	injections, sudden death after	1228	Report of committee on department of public health	988
Albany medical alumni dine	193	in Bordeaux	543	of committee on nominations	989
Albert, Professor	291	of Alcoholism	1035	of Treasurer of Rush monument committee	985
Albumin in urine, test for	1094	once more on	957	Rush monument committee	787, 839
Albuminoids, chemic color tests with	591	or serum therapy	778	Second Pan-American Medical Congress	1143
Alcohol, effect of, on the organs of special sense	1258	statistics, can they be relied upon?	180	Section on Dental and Oral Surgery	738, 793
Alcohol in obstetric disinfection	596	to control sale of, in Connecticut	1094	on Diseases of Children	589
Alcoholic drinks, toxic properties of	394	toxic effect of	789	on Dermatology and Syphilography	738
Alcoholism, a rational treatment of	593	treatment, criticism of the, from a different standpoint	174	on Laryngology and Otology	738
in Belgium	1187	treatment in Germany, official reports of the	1005	on Materia Medica, Pharmacy and Therapeutics	840, 1141
Alexander operation, consideration of the value of the, compared with that by anterior fixation of the uterus	515	Antivaccinists, an object lesson for	942	on Neurology and Medical Jurisprudence—announcement	392, 737, 839
Alimentary canal, experiments on the secretory excitability of the	630	Antivenomous substance, use of blood of viper and common adder as an	292	on Obstetrics and Diseases of Women	738, 794
Alkali in the blood, to determine the amount of	646	Antivivisection bill, against the	598	on Ophthalmology—provisional program	639
Allen, Dr. William L. A case of gastrostomy for the removal of hair ball	199	bill and the Senate	1089	on Practice of Medicine	793
Allport, Dr. Frank. Myringitis acuta—myringitis bullosa	123	bill, scientists disapprove the movement in Massachusetts	448	on State Medicine	589, 785, 793
Dr. Frank. A correction	887	Anti-vivisectionist, the character of	388	on Surgery and Anatomy	540, 793
Alopecia areata, treatment of	1246	Apolysin, a note on the action of	1219	The Atlanta meeting	281, 438, 489, 533, 635, 979
Alum bougies	1094	Appendix vermiformis cecii; technique of removing the	1202	Treasurer's notice	891
Alumnus, the oldest	839	Appendicitis	877		
Alveola and maxilla, specific treatment of necrosis of, with aromatic sulphuric acid	518	a study in	1269	BACH, Dr. James A. Clinical lecture	181
A. M. A. badge, the	688	chewing-gum the nucleus for an	946	Bacillus coli communis, notes on the distribution of	410
Amblyopia attending lactation	595	family tendency to	746	Bacterial diagnosis, a mild protest against, at the London Pathological Society	1045
Ambulance, a new English	290	protean types	353	Bacteriology	270, 330
corps, recruits to the	347	reasons for early operation in	780	diagnosis by	36
surgeon commended	1144	the medical side of	93	Badge, a permanent, for the American Medical Association	537
Ameba enteritis	1040	Appointments	291	Baker, Dr. Louis Balmat. Nature and treatment of disease	1214
American foods of good quality	691	Arabian Medical practice, modern	291	Ball, lost, hunting a	442
physician and citizen wanted in Cuba	1041	Arden, John, or John of Arden, on "Ye Goode Chirurgion"	1279	Ballenger, Dr. Wm. L. Electrolysis as a treatment for deviations, spurs and ridges of the nasal septum	58
physicians and surgeons, congress of	395	Areca nut, the alkaloid derived from the	847	Bangor general hospital	1281
Amherst College hospital for students	491	Argonin	646	Barr, Dr. G. Walter. The therapeutic abuse of opium	161
Amputations, report on, at the junction of the tarsal and metatarsal articulation	617	Arkansas prefers county medical examiners	1043	Bath, how the attendant got the	1093
Amusements, the hygienic importance of	993	Army, circular of information	698	Batman, Dr. W. F. Treatment of typhoid fever	188
Amygdophenin, the new remedy for rheumatism	482	medical school, closing exercises of the session 1895-96	599	Beach, Dr. H. H. A. Exploration and treatment of fissures from skull fractures	1059
Anæmia or anemia?	143	Army, U. S., changes in, 98, 148, 198, 298, 348, 398, 448, 598, 648, 698, 748, 798, 848, 898, 948, 1048, 1098, 1148, 1198, 1248, 1284	1284	Beal, Dr. A. M. Cor bovinum and horse-shoe kidney—necropsy	1021
Anagryin localized in the grain	491	Arnold, Dr. H. A. Whither are we drifting? Indications of a degenerate materia medica	176	Beard, Dr. Charles H. The treatment of trachoma and trachoma sequela,	60
Anal fissures, treatment of, with cocaine and ichthyol	896	Arsenical fly-paper used for suicidal purposes	944		
Anatomic material, defective legislation as to the supply of	814	Arterial pulse in saphenous vein	443		
button, a new	694	Arterio-venous anastomosis discovery anticipated by Rolan	845		
Andrews, Dr. Edmund. Napoleon's alleged epilepsy	655	Artificial serum, essential paroxysmal tachycardia treated with	1039		
Dr. R. R. Calcification	468	Asafetida in gynecology	495		
Anæmia, chronic, cured with hypodermic injections of mercury and quinin	645	Asbestos in boots and shoes	693		
Iron hypodermically given in	747	Ascites chylosus, case of	1166		
Iron in the dermiform organs in	637	Asepsis in country practice	596		
pernicious	1216
